SUMMARY

Among all 3D 8-node hexahedral solid elements in current finite element library, the ‘best’ one can produce good results for bending problems using coarse regular meshes. However, once the mesh is distorted, the accuracy will drop dramatically. And how to solve this problem is still a challenge that remains outstanding. This paper develops an 8-node, 24-DOF (three conventional DOFs per node) hexahedral element based on the virtual work principle, in which two different sets of displacement fields are employed simultaneously to formulate an unsymmetric element stiffness matrix. The first set simply utilizes the formulations of the traditional 8-node tri-linear isoparametric element, while the second set mainly employs the analytical trial functions in terms of 3D oblique coordinates (R, S, T). The resulting element, denoted by US-ATFH8, contains no adjustable factor, and can be used for both isotropic and anisotropic cases. Numerical examples show it can strictly pass both the first-order (constant stress/strain) patch test and the second-order patch test for pure bending, remove the volume locking, and provide the invariance for coordinate rotation. Especially, it is insensitive to various severe mesh distortions.

KEY WORDS: finite element; 8-node hexahedral element; unsymmetric element; analytical trial function; oblique coordinates; mesh distortion

1. INTRODUCTION

Because of relatively higher accuracy and lower computation cost, 8-node hexahedral isoparametric element is often preferred in analysis of 3D problems [1]. However, for traditional tri-linear isoparametric element, when dealing with solids and structures with complicated loadings or geometries, full integration model may suffer from various locking problems and will be very sensitive to mesh distortions, while reduced integration model may appear hourglass phenomena or lead to incorrect results. Among all 3D 8-node hexahedral solid elements in current finite element library, some incompatible elements [1-5] are usually considered as the models with the best precision because they can produce good results for bending problems using very coarse regular meshes. However, once the mesh is distorted, the accuracy will drop dramatically again. This is a living example of the sensitivity problem to mesh distortion, which is the core inherent difficulty existing in finite element methods. And how to solve this problem is still a challenge that remains outstanding. Actually, the same difficulty is also hard to be overcome even for 2D problems. MacNeal has proved that any 4-node, 8-DOF quadrilateral membrane isoparametric element of trapezoidal shape must either lock in pure bending tests or fail to pass constant stress/strain patch tests [6], and the similar limitation can be generalized to 3D 8-node hexahedral finite elements [7]. It almost closes out further effort to design new element models with high distortion resistance.

For past 60 years, numerous efforts have been made to improve performance and capacity of finite elements, such as the incompatible displacement methods proposed by Wilson et al. [2] and the modified version by Taylor et al. [3], the reduced or selective reduced integration patterns [8-10] and the corresponding hourglass control techniques [11-14], the enhanced assumed strain (EAS) methods [4, 5, 15, 16], the hybrid element methods [17, 18], the analytical interpolation method [19], the finite element-meshfree combination method [20], and so on.
However, it seems that no element mentioned above is truly beyond the limitation shown by MacNeal [6, 7].

Lee and Bathe [21] pointed out that the nonlinear transformation relationship between parametric and physical coordinates may be one of the reasons that cause the sensitivity problem to mesh distortions. In order to avoid the troubles caused by this nonlinear relationship, Long et al. successively established three forms of 2D quadrilateral area coordinate methods (QACM-I, QACM-II and QACM-III) [22-26] and a 3D hexahedral volume coordinate method (HVCM) [27], in which the transformations between these new local coordinates and the Cartesian (physical) coordinates are always linear, respectively. Subsequently, a series of new quadrilateral plane membrane elements [25, 26, 28-33] and 3D hexahedral elements [27] were developed. Although many elements greatly improve the distortion resistance for bending tests, all of them fail to strictly pass the constant stress/strain (C₀) patch tests. So, their convergence raised some queries and discussions [34, 35]. Cen et al. [29] and Chen et al. [36] tried to make them pass the C₀ patch test, but the distortion resistance will be destroyed again for bending tests.

For developing distortion-immune elements, some researchers began to look for new formulations from other theoretical space. Rajendran et al. [37-42] adopted the virtual work principle to establish a kind of unsymmetric finite element method, in which the test and the trial functions for displacement fields are different and the resulting element stiffness matrix is unsymmetric. For test functions, the conventional shape functions of isoparametric elements are selected to exactly satisfy the minimum inter- as well as intra-element displacement continuity requirements; and for trial functions, the polynomials in terms of Cartesian (physical) coordinates are chosen to satisfy the completeness requirements in physical space. Since there is no Jacobian determinant in the final formula for evaluating the element stiffness matrix, the resulting elements can still perform well even when they are severely distorted. However, their method is only effective for constructing high-order elements, such as 8-node plane quadrilateral element US-QUAD8 [37] and 20-node 3D hexahedral element US-HEXA20 [38]. Furthermore, because the number of element DOFs usually does not equal to the number of items for a complete
polynomial in terms of Cartesian coordinates, interpolation failure may take place when the element is distorted to certain shapes, and rotational frame dependence may also appear [43]. So, they are not convenient and effective for practical applications. Cen et al. [44] developed a new 8-node unsymmetric plane element US-ATFQ8 by introducing analytical trial functions and generalized conforming conditions. This element can overcome all above defects and even produce exact solutions in linear bending problems (third-order patch test).

Recently, some significant progresses have also been made for developing low-order elements. Cen et al. [45] successfully formulated an unsymmetric 4-node, 8-DOF plane element. The key technique is that the second displacement field set (trial functions) employs a composite coordinate interpolation scheme with analytical trial function method, in which the items 1, x, y and two sets of analytical solutions for pure bending state in terms of the second form of quadrilateral area coordinates (QACM-II) are applied together. The resulting element US-ATFQ4, which can be used for both isotropic and anisotropic cases, exhibits amazing performance in rigorous tests. It can satisfy both the classical first-order (constant stress/strain) patch test and the second-order patch test for pure bending, and is insensitive to various severe mesh distortions. Due to the isotropy of the natural local coordinate QACM-II, US-ATFQ4 can provide the invariance for the coordinate rotation. The appearance of this element seems that the limitation defined by MacNeal’s theorem can be broken through. Almost at the same time, Xie et al. [46] also utilized similar procedure developed a 4-node plane element TQ4 and an 8-node hexahedral element TH8. The major different is that they used a kind of local oblique coordinate method defined by Yuan et al. [47, 48] together with Cartesian and isoparametric coordinates in their interpolation formulae. However, these two elements can be used only for isotropic problems. Furthermore, an adjustable factor $\beta$ varying from 0.01 to 0.0001 ($\beta = 0.01$ was adopted by [46]) is introduced into the interpolation matrix of element TH8 for enhancing the element accuracy. In fact, because this factor has no definite physical significance, incorrect results may appear if the factor is not appropriate (see Section 4.2 and Tables 4 and 6).
The purpose of this paper is to present an 8-node hexahedral element with high distortion resistance as well as no obvious numerical defects. First, nine sets of analytical general solutions for linear stresses, linear strains and quadratic displacements in terms of 3D local oblique coordinates \((R, S, T)\) [47, 48], which are not found in other literatures, are derived. These analytical solutions are also the Trefftz solutions [49]. Then, a new 8-node hexahedral element is developed based on the virtual work principle, in which two different sets of displacement fields are employed simultaneously to formulate an unsymmetric element stiffness matrix. The first set simply utilizes the formulations of the 8-node tri-linear isoparametric element, while the second set mainly employs the analytical trial functions in terms of 3D local oblique coordinates. Because the relationship between the local oblique and Cartesian coordinates is always linear, and there is no Jacobian determinant needed for computing the element stiffness matrix, the new element is expected to be insensitive to mesh distortion. The resulting element, denoted by US-ATFH8, contains no adjustable factor, and can be used for both isotropic and anisotropic cases. Numerical examples show it can exactly pass both the first-order (constant stress/strain) patch test and the second-order patch test for pure bending, remove the volume locking, and provide the invariance for coordinate rotation. Especially, it is insensitive to various severe mesh distortions.

2. ANALYTICAL GENERAL SOLUTIONS IN TERMS OF 3D OBLIQUE COORDINATES

As described in previous section, in order to construct finite element models insensitive to mesh distortion, a local coordinate system which is linearly related to the global Cartesian coordinate system should be considered. For 3D problems, the most feasible one is the oblique (skew) coordinate system defined by Yuan et al. [47, 48].
2.1. Definition of 3D oblique coordinate system [47, 48]

For an 8-node hexahedral element shown in Figure 1, the Cartesian coordinates \((x, y, z)\) can be expressed in terms of the isoparametric coordinates \((\xi, \eta, \zeta)\) as

\[
\begin{align*}
\{x\} &= \sum_{i=1}^{8} N_i \{x_i\}, \\
\{y\} &= \sum_{i=1}^{8} N_i \{y_i\}, \\
\{z\} &= \sum_{i=1}^{8} N_i \{z_i\},
\end{align*}
\]

where

\[
N_i = \frac{1}{8} (1 + \xi_i \xi)(1 + \eta_i \eta)(1 + \zeta_i \zeta) \quad i = (1, 2, ..., 8),
\]

\[
\begin{align*}
\{x_i\} &= \frac{1}{8} \sum_{i=1}^{8} \{x_i\}, \\
\{y_i\} &= \frac{1}{8} \sum_{i=1}^{8} \{y_i\}, \\
\{z_i\} &= \frac{1}{8} \sum_{i=1}^{8} \{z_i\},
\end{align*}
\]

in which \((\xi, \eta, \zeta)\) and \((x_i, y_i, z_i)\) \((i=1-8)\) are the isoparametric and Cartesian coordinates of the eight corner nodes, respectively.

Yuan et al. [47, 48] defined a kind of 3D oblique coordinates \((R, S, T)\) as follows

\[
\begin{bmatrix}
R \\
S \\
T
\end{bmatrix} = (J_0^{-1})^T \begin{bmatrix}
x \\
y \\
z
\end{bmatrix} - \begin{bmatrix}
x \\
y \\
z
\end{bmatrix},
\]

where \(J_0\) denotes the Jacobian matrix at the origin of the isoparametric coordinates \((\xi, \eta, \zeta) = (0, 0, 0)\),

\[
J_0 = \left[\begin{array}{ccc}
\frac{\partial x}{\partial \xi} & \frac{\partial y}{\partial \xi} & \frac{\partial z}{\partial \xi} \\
\frac{\partial x}{\partial \eta} & \frac{\partial y}{\partial \eta} & \frac{\partial z}{\partial \eta} \\
\frac{\partial x}{\partial \zeta} & \frac{\partial y}{\partial \zeta} & \frac{\partial z}{\partial \zeta}
\end{array}\right]_{\xi=\eta=\zeta=0} = \begin{bmatrix}
a_1 & b_1 & c_1 \\
a_2 & b_2 & c_2 \\
a_3 & b_3 & c_3
\end{bmatrix},
\]

\[
J_0 = J_0 = \begin{bmatrix}
a_1 (b_2 c_3 - b_3 c_2) + a_2 (b_3 c_1 - b_1 c_3) + a_3 (b_1 c_2 - b_2 c_1) \\
a_2 a_1 + a_2 a_3 + a_3 a_2 = b_1 b_2 + b_2 b_3 + b_3 b_1 = c_1 c_2 + c_2 c_3 + c_3 c_1
\end{bmatrix},
\]

\[
a_1 = \bar{b}_1 \bar{c}_3 - \bar{b}_3 \bar{c}_2, \quad b_1 = \bar{a}_1 \bar{c}_2 - \bar{a}_2 \bar{c}_3, \quad c_1 = \bar{a}_3 \bar{b}_3 - \bar{a}_3 \bar{b}_2 \\
a_2 = \bar{b}_2 \bar{c}_1 - \bar{b}_1 \bar{c}_3, \quad b_2 = \bar{a}_2 \bar{c}_3 - \bar{a}_3 \bar{c}_1, \quad c_2 = \bar{a}_3 \bar{b}_1 - \bar{a}_3 \bar{b}_3 \\
a_3 = \bar{b}_3 \bar{c}_2 - \bar{b}_2 \bar{c}_1, \quad b_3 = \bar{a}_3 \bar{c}_1 - \bar{a}_1 \bar{c}_3, \quad c_3 = \bar{a}_1 \bar{b}_2 - \bar{a}_2 \bar{b}_1
\]
It can be easily found that the relationship of the oblique coordinates \((R, S, T)\) and the Cartesian coordinates \((x, y, z)\) is always linear. As shown in Figure 1, \((R, S, T)\) and the isoparametric coordinates \((\zeta, \eta, \zeta)\) share the same directions, respectively, and their origins also coincide with each other.

The transformation of first-order derivatives is

\[
\begin{bmatrix}
\frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\
\frac{\partial R}{\partial x} & \frac{\partial S}{\partial x} & \frac{\partial T}{\partial x} \\
\frac{\partial R}{\partial y} & \frac{\partial S}{\partial y} & \frac{\partial T}{\partial y} \\
\frac{\partial R}{\partial z} & \frac{\partial S}{\partial z} & \frac{\partial T}{\partial z}
\end{bmatrix}
= \frac{1}{J_0} \begin{bmatrix}
a_1 & a_2 & a_3 \\
b_1 & b_2 & b_3 \\
c_1 & c_2 & c_3
\end{bmatrix}
\begin{bmatrix}
\frac{\partial R}{\partial r} \\
\frac{\partial S}{\partial r} \\
\frac{\partial T}{\partial r}
\end{bmatrix}. \tag{8}
\]

And the transformation of second-order derivatives is

\[
\begin{bmatrix}
\frac{\partial^2}{\partial x^2} & \frac{\partial^2}{\partial y^2} & \frac{\partial^2}{\partial z^2} \\
\frac{\partial^2 R^2}{\partial x^2} & \frac{\partial^2 S^2}{\partial y^2} & \frac{\partial^2 T^2}{\partial z^2} \\
\frac{\partial^2 R^2}{\partial x \partial y} & \frac{\partial^2 S^2}{\partial y \partial z} & \frac{\partial^2 T^2}{\partial z \partial x}
\end{bmatrix}
= \frac{1}{J_0^2} \begin{bmatrix}
a_1 b_1 & a_2 b_2 & a_3 b_3 \\
2a_1 a_2 b_1 & 2a_2 a_3 b_2 & 2a_3 a_1 b_3 \\
2a_1 a_2 & 2a_2 a_3 & 2a_3 a_1 \\
a_1 c_1 & a_2 c_2 & a_3 c_3 \\
2a_1 a_2 c_1 & 2a_2 a_3 c_2 & 2a_3 a_1 c_3 \\
2a_1 c_1 b_1 + b_2 a_1 c_1 & 2a_2 c_2 b_2 + b_3 a_2 c_2 & 2a_3 c_3 b_3 + b_1 a_3 c_3
\end{bmatrix}
\begin{bmatrix}
\frac{\partial^2 R}{\partial r^2} \\
\frac{\partial^2 S}{\partial r^2} \\
\frac{\partial^2 T}{\partial r^2}
\end{bmatrix}. \tag{9}
\]

2.2. The analytical general solutions in terms of 3D oblique coordinate system

In order to improve element performance, the analytical solutions of stresses, strains, or displacements satisfying governing equations in elasticity are often taken as the trial functions in some finite element methods, such as the Trefftz finite element method [49] and the hybrid stress-function element method proposed by Cen et al. [50-55]. It is also noteworthy that the usage of the analytical solutions in terms of the local coordinates \([32, 45]\) may eliminate directional dependence problem. In this section, nine sets of analytical general solutions for linear stresses, linear strains and quadratic displacements in terms of 3D local oblique coordinates will be derived.
For three-dimensional problems without body forces, the homogeneous equilibrium equations in the oblique coordinate system are given by

$$\begin{align*}
\frac{\partial \sigma_R}{\partial R} + \frac{\partial \tau_{SR}}{\partial S} + \frac{\partial \tau_{TR}}{\partial T} &= 0 \\
\frac{\partial \sigma_S}{\partial S} + \frac{\partial \tau_{TS}}{\partial T} + \frac{\partial \tau_{RS}}{\partial R} &= 0 \\
\frac{\partial \sigma_T}{\partial T} + \frac{\partial \tau_{TR}}{\partial R} + \frac{\partial \tau_{ST}}{\partial S} &= 0
\end{align*}$$

(10)

The first 27 sets of analytical solutions for above stresses in terms of 3D oblique coordinate system are listed in Table 1, in which the first 3 sets, 4th to 12th sets and 13th to 27th sets are related to the rigid body, the linear and the quadratic displacement modes, respectively. Since the constant stress solutions will not be used later, their explicit forms are not given in the table.

According to equation (4), the stress components in Cartesian coordinates \((x, y, z)\) can be expressed by the stress components in oblique coordinates \((R, S, T)\):

$$\begin{align*}
\begin{bmatrix}
\sigma_x & \tau_{xy} & \tau_{zx} \\
\tau_{xy} & \sigma_y & \tau_{yz} \\
\tau_{zx} & \tau_{yz} & \sigma_z
\end{bmatrix} &= \begin{bmatrix}
\bar{a}_1 & \bar{b}_1 & \bar{c}_1 \\
\bar{a}_2 & \bar{b}_2 & \bar{c}_2 \\
\bar{a}_3 & \bar{b}_3 & \bar{c}_3
\end{bmatrix}^T \begin{bmatrix}
\sigma_R & \tau_{RS} & \tau_{RT} \\
\tau_{RS} & \sigma_S & \tau_{ST} \\
\tau_{RT} & \tau_{ST} & \sigma_T
\end{bmatrix} \begin{bmatrix}
\bar{a}_1 & \bar{b}_1 & \bar{c}_1 \\
\bar{a}_2 & \bar{b}_2 & \bar{c}_2 \\
\bar{a}_3 & \bar{b}_3 & \bar{c}_3
\end{bmatrix},
\end{align*}$$

(11)

i.e.

$$\begin{align*}
\begin{bmatrix}
\sigma_x \\
\sigma_y \\
\sigma_z \\
\tau_{xy} \\
\tau_{yz} \\
\tau_{zx}
\end{bmatrix} &= \begin{bmatrix}
\bar{a}_1 \bar{a}_2 \bar{a}_3 \\
\bar{b}_1 \bar{b}_2 \bar{b}_3 \\
\bar{c}_1 \bar{c}_2 \bar{c}_3 \\
\bar{a}_1 \bar{b}_1 \bar{c}_1 \\
\bar{a}_2 \bar{b}_2 \bar{c}_2 \\
\bar{a}_3 \bar{b}_3 \bar{c}_3
\end{bmatrix} \begin{bmatrix}
\sigma_R \\
\sigma_S \\
\sigma_T \\
\tau_{RS} \\
\tau_{ST} \\
\tau_{RT}
\end{bmatrix}.
\end{align*}$$

(12)

Then, the strains in Cartesian coordinate system can be obtained by following stress-strain relations (generalized Hooke law):
\[ \varepsilon = \begin{bmatrix} \varepsilon_x \\ \varepsilon_y \\ \varepsilon_z \\ \gamma_{xy} \\ \gamma_{xz} \\ \gamma_{yz} \end{bmatrix} = \frac{1}{E} \begin{bmatrix} 1 & -\mu & -\mu & 0 & 0 & 0 \\
-\mu & 1 & -\mu & 0 & 0 & 0 \\
-\mu & -\mu & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 2(1+\mu) & 0 & 0 \\
0 & 0 & 0 & 0 & 2(1+\mu) & 0 \\
0 & 0 & 0 & 0 & 0 & 2(1+\mu) \end{bmatrix} \begin{bmatrix} \sigma_x \\ \sigma_y \\ \sigma_z \\ \tau_{xy} \\ \tau_{xz} \\ \tau_{yz} \end{bmatrix} = C\sigma, \text{ for isotropic case; } \quad (13a) \]

\[ \varepsilon = \begin{bmatrix} \varepsilon_x \\ \varepsilon_y \\ \varepsilon_z \\ \gamma_{xy} \\ \gamma_{xz} \\ \gamma_{yz} \end{bmatrix} = \begin{bmatrix} C_{11} & C_{12} & C_{13} & C_{14} & C_{15} & C_{16} \\
C_{21} & C_{22} & C_{23} & C_{24} & C_{25} & C_{26} \\
C_{31} & C_{32} & C_{33} & C_{34} & C_{35} & C_{36} \\
C_{41} & C_{42} & C_{43} & C_{44} & C_{45} & C_{46} \\
C_{51} & C_{52} & C_{53} & C_{54} & C_{55} & C_{56} \\
C_{61} & C_{62} & C_{63} & C_{64} & C_{65} & C_{66} \end{bmatrix} \begin{bmatrix} \sigma_x \\ \sigma_y \\ \sigma_z \\ \tau_{xy} \\ \tau_{xz} \\ \tau_{yz} \end{bmatrix} = C\sigma, \text{ for anisotropic case, } \quad (13b) \]

where \( C \) is the elasticity matrix of compliances; \( E \) and \( \mu \) are Young’s modulus and Poisson’s ratio, respectively.

Thus, these strains can also be expressed by the stress components in local oblique coordinates by substituting Equation (12) into (13).

Finally, by using Equation (8) and integrating following geometrical equations

\[ \begin{aligned}
\varepsilon_x &= \frac{\partial u}{\partial x}, & \varepsilon_y &= \frac{\partial v}{\partial y}, & \varepsilon_z &= \frac{\partial w}{\partial z} \\
\gamma_{xy} &= \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}, & \gamma_{xz} &= \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y}, & \gamma_{yz} &= \frac{\partial w}{\partial x} + \frac{\partial u}{\partial y} 
\end{aligned} \quad (14) \]

the displacements \( u, v \) and \( w \) in Cartesian coordinate system can be solved.

Following above procedure, the analytical general solutions of stresses, strains and displacements in the global coordinate system, but in terms of the local oblique coordinates \( R, S \) and \( T \), can be obtained.

Only nine sets \((i=13~21)\) of the analytical general solutions for local linear stresses in Table 1 related to pure bending and twisting states will be considered in the new finite element formulations, which are given in appendix A.
3. CONSTRUCTION OF A NEW UNSYMMETRIC 8-NODE HEXAHEDRAL ELEMENT US-ATFH8

For a three-dimensional 8-node, 24-DOF (3 DOFs per node) finite element model shown in Figure 2, the virtual work principle [37, 38] can be written as

$$\iiint_{V^e} \sigma^T \delta \text{d}V - \iint_{\Gamma^e} \delta \textbf{u}^T \textbf{b} \text{d}S - \int_{\Gamma^e} \delta \textbf{u}^T \textbf{T} \delta \Gamma - \delta \textbf{u}^T \textbf{f}_e = 0,$$

(15)

in which \(V^e\) denotes the element volume; \(\Gamma^e\) represents the element boundary face; \(\sigma\) is the real stress vector of the element; \(\textbf{b}, \textbf{T}\) and \(\textbf{f}_e\) are the real body, surface and concentrated forces of the element, respectively; \(\delta \textbf{u}_e\) is the vector of virtual displacements at the points of the concentrated forces; \(\delta \textbf{u}\) is the virtual displacement fields and \(\delta \textbf{\varepsilon}\) is the corresponding virtual strain fields.

First, the virtual displacement fields

$$\delta \textbf{u} = \left[ \begin{array}{c} \delta u_1 \\ \delta v_1 \\ \delta w_1 \\ \vdots \\ \delta u_8 \\ \delta v_8 \\ \delta w_8 \end{array} \right] = \textbf{N} \delta \textbf{q}^e,$$

(16)

where

$$\delta \textbf{q}^e = \left[ \begin{array}{cccc} \delta u_1 & \delta v_1 & \delta w_1 & \ldots & \delta u_8 & \delta v_8 & \delta w_8 \end{array} \right]^T,$$

(17)

$$\textbf{N} = \left[ \begin{array}{cccc} \bar{N}_1 & 0 & 0 & \ldots & \bar{N}_8 & 0 & 0 \\ 0 & \bar{N}_1 & 0 & \ldots & 0 & \bar{N}_8 & 0 \\ 0 & 0 & \bar{N}_1 & \ldots & 0 & 0 & \bar{N}_8 \end{array} \right],$$

(18)

in which \(\delta u, \delta v, \delta w\) are the nodal virtual displacements along \(x, y, z\)-directions, respectively; \(\bar{N}_i\) are just the shape functions of the traditional 8-node tri-linear isoparametric element that satisfy all continuity requirements, and have been given by Equation (2).

Thus, the corresponding virtual strain fields \(\delta \textbf{\varepsilon}\) are

$$\delta \textbf{\varepsilon} = \left[ \begin{array}{cccc} \delta \varepsilon_x & \delta \varepsilon_y & \delta \varepsilon_z & \delta \gamma_{xy} & \delta \gamma_{xz} & \delta \gamma_{yz} \end{array} \right]^T = \textbf{B} \delta \textbf{q}^e,$$

(19)

where \(\textbf{B}\) is the strain matrix of the traditional 8-node tri-linear isoparametric element,
\[ \overline{\mathbf{B}} = \mathbf{L} \mathbf{N} = \frac{1}{|J|} \mathbf{B}^*, \quad (20) \]

with

\[
\mathbf{L} = \begin{bmatrix}
\frac{\partial}{\partial x} & 0 & 0 & \frac{\partial}{\partial y} & 0 & \frac{\partial}{\partial z} \\
0 & \frac{\partial}{\partial y} & 0 & \frac{\partial}{\partial z} & 0 & \frac{\partial}{\partial z} \\
0 & 0 & \frac{\partial}{\partial z} & 0 & \frac{\partial}{\partial y} & \frac{\partial}{\partial x}
\end{bmatrix}^T,
\quad (21)
\]

and \(|J|\) is the Jacobian determinant,

\[
|J| = \begin{vmatrix}
\frac{\partial x}{\partial \xi} & \frac{\partial y}{\partial \xi} & \frac{\partial z}{\partial \xi} \\
\frac{\partial x}{\partial \eta} & \frac{\partial y}{\partial \eta} & \frac{\partial z}{\partial \eta} \\
\frac{\partial x}{\partial \zeta} & \frac{\partial y}{\partial \zeta} & \frac{\partial z}{\partial \zeta}
\end{vmatrix},
\quad (22)
\]

\[
x = \sum_{i=1}^{8} \overline{N}_i x_i, \quad y = \sum_{i=1}^{8} \overline{N}_i y_i, \quad z = \sum_{i=1}^{8} \overline{N}_i z_i .
\quad (23)
\]

Second, assume that the real stresses \(\hat{\sigma}\) in Equation (15) are derived from the following assumed displacement fields expressed in terms of the local oblique coordinates \(R, S\) and \(T\);

\[
\hat{\mathbf{u}} = \begin{bmatrix} \hat{u} \\ \hat{v} \\ \hat{w} \end{bmatrix} = \mathbf{P} \alpha = \begin{bmatrix}
1 & 0 & 0 & R & 0 & 0 & S & 0 & 0 & T & 0 & 0 & U_{13} & \cdots & U_{21} & RST & 0 & 0 \\
0 & 1 & 0 & 0 & R & 0 & 0 & S & 0 & 0 & T & 0 & V_{13} & \cdots & V_{21} & 0 & RST \\
0 & 0 & 1 & 0 & 0 & R & 0 & 0 & S & 0 & 0 & T & W_{13} & \cdots & W_{21} & 0 & 0 & RST
\end{bmatrix} \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_{24} \end{bmatrix},
\quad (24)
\]

where \(\alpha_i (i=1\sim 24)\) are twenty-four undetermined coefficients; \(U_i, V_i\) and \(W_i (i=13\sim 21)\) are the analytical general solutions for quadratic displacements given by Equations (A20) to (A22); the first twelve columns of interpolation matrix \(\mathbf{P}\) are also displacement analytical general solutions satisfying all governing equations, as shown in Table 1.

The last three columns containing the cubic term \(RST\) are not the analytical solutions, but they can keep linear independence between each two columns, and make the resulting stress components invariant for global coordinate rotation.

Substitution of the Cartesian coordinates of eight corner nodes into Equation (24) yields
\[
\hat{d} \alpha = q^e, \quad (25)
\]

where

\[
\hat{d} = \begin{bmatrix}
P(x_1, y_1, z_1) \\
P(x_2, y_2, z_2) \\
\vdots \\
P(x_8, y_8, z_8)
\end{bmatrix},
\quad (26)
\]

\[
q^e = [u_1 \ v_1 \ w_1 \ \cdots \ u_8 \ v_8 \ w_8]^T, \quad (27)
\]

in which \(u_i, v_i\) and \(w_i\) (\(i = 1\sim 8\)) are the nodal displacements along \(x\)-, \(y\)- and \(z\)- directions, respectively. Then, \(\alpha_i\) (\(i=1\sim 24\)) can be solved by

\[
\alpha = \hat{d}^{-1} q^e. \quad (28)
\]

And the assumed displacement fields \(\hat{u}\) given by Equation (24) can be rewritten as

\[
\hat{u} = \begin{bmatrix}
\hat{v} \\
\hat{w}
\end{bmatrix} = P\alpha = P\hat{d}^{-1} q^e. \quad (29)
\]

Then, the corresponding strains can be obtained by substituting equation (29) into (14)

\[
\hat{\varepsilon} = \begin{bmatrix}
\hat{\varepsilon}_x \\
\hat{\varepsilon}_y \\
\hat{\varepsilon}_z \\
\hat{\gamma}_{xy} \\
\hat{\gamma}_{yz} \\
\hat{\gamma}_{zx}
\end{bmatrix} = \tilde{P}\hat{d}^{-1} q^e = \tilde{B} q^e, \quad (30)
\]

where \(\tilde{B} = \tilde{P}\hat{d}^{-1}\) is the strain matrix, and

\[
\tilde{P} = 
\begin{bmatrix}
0 & 0 & a_1 & 0 & 0 & a_2 & 0 & 0 & a_3 & 0 & 0 & \varepsilon_{13} & \cdots & \varepsilon_{121} & u_1 & 0 & 0 \\
0 & 0 & 0 & 0 & b_1 & 0 & 0 & b_2 & 0 & 0 & b_3 & 0 & \varepsilon_{y13} & \cdots & \varepsilon_{y121} & 0 & u_b & 0 \\
0 & 0 & 0 & 0 & c_1 & 0 & 0 & c_2 & 0 & 0 & c_3 & 0 & \varepsilon_{z13} & \cdots & \varepsilon_{z121} & 0 & u_c & 0 \\
0 & 0 & b_1 & a_1 & 0 & b_2 & 0 & a_2 & 0 & b_3 & a_3 & 0 & \gamma_{xy13} & \cdots & \gamma_{xy121} & u_b & u_a & 0 \\
0 & 0 & 0 & c_1 & b_1 & 0 & c_2 & b_2 & 0 & c_3 & b_3 & 0 & \gamma_{yz13} & \cdots & \gamma_{yz121} & 0 & u_c & u_b \\
0 & 0 & c_1 & 0 & a_1 & c_2 & 0 & a_2 & 0 & c_3 & 0 & \gamma_{xz13} & \cdots & \gamma_{xz121} & u_c & 0 & u_a
\end{bmatrix}, \quad (31)
\]

with
\[ u_a = \frac{1}{J_0} (a_1 ST + a_2 RT + a_3 RS), \quad u_b = \frac{1}{J_0} (b_1 ST + b_2 RT + b_3 RS), \quad u_c = \frac{1}{J_0} (c_1 ST + c_2 RT + c_3 RS), \]  \hspace{1cm} (32)

in which \((\varepsilon_{x1}, \varepsilon_{y1}, \varepsilon_{z1}, \gamma_{xy1}, \gamma_{xz1}) (i = 13\sim 21)\) are the nine sets of analytical solutions for linear strains given by Equations (A3), (A5), (A7), (A9), (A11), (A13), (A15), (A17) and (A19), respectively.

According to the constitutive relation Equation (13), the corresponding stresses can be solved

\[ \sigma = \begin{bmatrix} \sigma_x \\ \sigma_y \\ \sigma_z \\ \tau_{xy} \\ \tau_{xz} \\ \tau_{yz} \end{bmatrix} = D\ddot{e} = D\hat{B}q^e = D\hat{P}d^{-1}q^e, \]  \hspace{1cm} (33)

where \(D\) is the elasticity matrix,

\[ D = C^{-1}. \]  \hspace{1cm} (34)

Substitution of Equations (16), (19) and (30) into (15) yields

\[
\begin{align*}
\iiiint_V \partial\varepsilon^T \dot{\sigma} dV - \iiiint_V \partial\varepsilon^T \dot{\sigma} dV - \mathcal{J}e & = \mathcal{J}e \varepsilon D\ddot{e} dV - \mathcal{J}e \varepsilon Td\Gamma - \partial\dot{u}_T^T \Gamma = (\hat{\varepsilon} q^e)^T (\mathcal{P}^T \mathcal{D} \hat{B} \dot{q}^e dV - \mathcal{J}e \varepsilon Td\Gamma - \partial\dot{u}_T^T \Gamma = (\hat{\varepsilon} q^e)^T (K^e q^e - F^e) \\
\end{align*}
\]

in which

\[ K^e = \mathcal{J}e \mathcal{P}^T \mathcal{D} \hat{B} dV, \]  \hspace{1cm} (36)

\[ F^e = \mathcal{J}e \mathcal{P}^T \mathcal{D} \hat{B} dV + \mathcal{J}e \varepsilon Td\Gamma + \partial\dot{u}_T^T \Gamma. \]  \hspace{1cm} (37)

Due to the arbitrariness of \(\hat{\varepsilon} q^e\) in Equation (35), the following finite element equation can be obtained

\[ K^e q^e - F^e = 0 , \]  \hspace{1cm} (38)

where \(F^e\) is the nodal equivalent load vector of the element; \(K^e\) is the element stiffness matrix, and it is an unsymmetric matrix. Substitution of Equations (20) and (33) into (36), the final element stiffness matrix can be
Because there is no Jacobian determinant existing in above expression, the resulting model will avoid troubles caused by ill-conditioned shape and be insensitive to mesh distortions. All above formulations can be expressed in terms of isoparametric coordinates $\xi, \eta$ and $\zeta$ by using equations (4) and (23), and a $2 \times 2 \times 2$ Gauss integration scheme is found to be enough for evaluating $\mathbf{K}^e$ given by Equation (39), although the $3 \times 3 \times 3$ scheme is theoretically needed.

The equivalent nodal load vector $\mathbf{F}^e$ can be determined by the same procedure for the traditional 8-node tri-linear isoparametric element. And the stresses at any point can be directly calculated by substituting the isoparametric, or Cartesian coordinates of this point within an element into Equation (33).

The new element is denoted by US-ATFH8.

4. NUMERICAL EXAMPLES

In this section, some classical benchmark problems are employed to assess the performance of the new element US-ATFH8, and results obtained by other 8-node hexahedral elements listed in Table 2 are also given for comparisons.

4.1 Constant stress/strain patch test (Figure 3)

A unit cube, as shown in Figure 3, is divided by seven irregular hexahedral elements. Nodes 1 to 8 are the inner nodes, and their locations are also given in Figure 3. The displacement fields corresponding to the constant
strain are:

\[ u = 10^{-3} (2x + y + z)/2, \quad v = 10^{-3} (x + 2y + z)/2, \quad w = 10^{-3} (x + y + 2z)/2. \]  \hfill (40)

And the corresponding stress solutions are:

\[ \sigma_x = \sigma_y = \sigma_z = 2000, \quad \tau_{xy} = \tau_{yz} = \tau_{zx} = 400. \]  \hfill (41)

The displacements of the boundary nodes are treated as the displacement boundary conditions. Exact results of the displacements and stresses at the inner nodes can be obtained by the new element US-ATFH8. Furthermore, the exact stresses at any point (by substituting the Cartesian coordinates into Equation (33)) can also be obtained. It can be concluded that the element US-ATFH8 can strictly pass the constant stress/strain patch test.

Elements Wilson_H8 [2] and HVCC8 series [27] in Table 2 cannot pass this patch test.

4.2 Cheung and Chen beam tests [17] (Figure 4)

This example was proposed by Cheung and Chen [17] for testing the performance of 8-node hexahedral elements. The geometric, material, and displacement boundary conditions are given in Figure 4. Twelve meshes divisions are designed to analyze this cantilever beam subjected to a pure bending moment \( M \) and a transverse shear force \( P \) at the free end, in which the \( x \) coordinates of nodes 1, 2, 3 and 4 in Meshes (2) to (10) are listed in Table 3. The normalized deflections at point A and the results of stresses at point B are given in Tables 4 and 5, respectively, and the results of deflections at points \( a_1, a_2, a_3 \) and \( a_4 \) in selected mesh divisions under loading \( P \) are also given in Table 6.

From Tables 4 and 5, it can be seen that exact displacements and stresses under pure bending state can be obtained by element TH8 (\( \beta = 0.01 \) and \( 0.0001 \)) [46] and the new element US-ATFH8, no matter how meshes are distorted, and no matter whether the four corner nodes of the interface are coplanar or not. Furthermore, it is worth mentioning that the new element US-ATFH8 can produce exact pure bending solutions in all directions when various distorted meshes are used. For the linear bending case, the new element US-ATFH8 can also present
relatively good and stable solutions in all mesh cases. But the results obtained by element TH8 deeply depend on the adjustable factor $\beta$ and are not stable. Especially, when $\beta=0.0001$, even wrong solutions will appear in some cases (see displacement result for load $P$ using Mesh (12) in Table 4). This problem is more clear in Table 6, many incorrect results for deflections at four different end points of the beam obtained by element TH8 appear when $\beta=0.0001$, and the results obtained by TH8 ($\beta=0.01$) are not stable in some occasions.

4.3 Rotational frame dependence test on a cantilever beam with fully fixed end (Figure 5)

Since the trial functions for displacements $\hat{\mathbf{u}}$ given in Equation (24) may be not completed in the global Cartesian coordinates, rotational frame dependence test should be performed for the new element US-ATFH8.

The geometric and displacement boundary conditions of a cantilever beam divided by two distorted elements are given in Figure 5. The Young’s modulus $E=100.0$, and the Poisson ratio $\mu=0.3$. Let the Cartesian coordinate system $\mathbf{xyz}$ rotate counterclockwise from $\alpha_1=0^\circ$ to $90^\circ$ in steps of $10^\circ$ around $z$-axis, and then rotate counterclockwise $\alpha_2=40^\circ$ around $y$-axis, the displacements at point A are solved at each step. The magnitude of displacement $\sqrt{u^2 + v^2 + w^2}$ at point A is monitored to study the rotational frame-dependent behavior. The results obtained by the new element US-ATFH8 are given in Table 7. The magnitude of displacements based on an ‘overkill’ solution is used as a reference solution, which is obtained by using 50000 20-node hexahedral isoparametric elements of Abaqus [1]. It can be seen that the present model US-ATFH8 provides the invariance for the coordinate rotation.

4.4 Bending problems for skew beam, curving beam and twisted beam

4.4.1 Cook’s skew beam problem (Figure 6)

This example shown in Figure 6 was proposed by Cook [56] to test the convergence of elements. A skew
cantilever is subjected to a shear uniformly distributed load at the free edge. The geometric, material and displacement boundary conditions are given in Figure 6. The results of vertical deflection at point C, the maximum principal stress at point A and the minimum principal stress at point B are all listed in Table 8. Those results obtained by the models that can pass the constant strain/stress patch test are also given for comparison. It can be seen that the present element US-ATFH8 exhibits good convergence.

4.4.2 Thin curved beam (Figure 7)

A thin curved beam with fully fixed end is shown in Figure 7. The inner radius $R_i$, thickness $h$ and width $t$ of the beam are 4.12, 0.2 and 0.1, respectively. The Young’s modulus $E=1.0 \times 10^7$, and the Poisson ratio $\mu=0.3$. Two load cases are considered: in-plane shear $P_1$ and out-of-plane shear $P_2$. The results of the deflection at point A are listed in Tables 9 and 10, respectively. Again, the new element US-ATFH8 performs well for this test.

4.4.3 Twisted beam problem (Figure 8)

This example was proposed by MacNeal and Harder [57] to test the effect of warping. As shown in Figure 8, a cantilever beam is twisted 90° from root to tip. This twisted beam is fixed at the root, and subjected to unit in-plane and out-of-plane forces at the tip. The length, width and thickness are 12, 1.1 and 0.32, respectively. The Young’s modulus $E=2.9 \times 10^7$, and the Poisson ratio $\mu=0.22$. Different meshes used for this example are also given in Figure 8, in which meshes (a), (b), (c) and (d) are distorted meshes newly designed by cutting the beam with different planes. And most of these cutting planes are parallel to new plane $xy$ after $x$-axis rotates 45° or $-45°$ around $y$-axis. The normalized solutions at tip point A are listed in Table 11 and 12. It can be seen that the new element US-ATFH8 can produce better results, even when the severely distorted meshes are used.
4.5 Nearly incompressible problems (Figure 9)

A thick-walled cylinder is subjected to a uniformly distributed internal pressure \( p = 1 \). This example, proposed by MacNeal [57], is used to test volume locking problem when the Poisson’s ratio is very close to 0.5. As shown in Figure 9, due to symmetry, only a quarter of the cylinder with unit thickness is considered. The nodal displacements along thickness direction are all constrained. The exact solution of the radial displacement \( u_r \) is same as that for the plane strain state, and given by [57]

\[
    u_r = \frac{(1 + \mu) p R_2^2}{E (R_2^2 - R_1^2)} \left[ \frac{R_2^2}{r} + (1 - 2\mu) r \right],
\]

where \( R_1 \) is the inner radius, \( R_2 \) is the outer radius. In this example, let \( R_1 = 3, R_2 = 9 \). When the Poisson’s ratio is \( \mu = 0.49, 0.499, 0.4999 \), the corresponding radial displacement \( u_r \) at \( r = R_1 \) are \( 5.0399 \times 10^{-3}, 5.0602 \times 10^{-3}, 5.0623 \times 10^{-3} \), respectively.

The normalized results of the radial displacement \( u_r \) at \( r = R_1 \) are given in Table 13. It can be seen that the standard 8-node tri-linear isoparametric element suffers from volumetric locking problem, while other improved models can give good results. Although the solutions obtained by element US-ATFH8 are not the best answers, it is clearly shown that the new element is free of the volumetric locking.

5. CONCLUSIONS

After successful development of plane 4-node, 8-DOF quadrilateral element US-ATFQ4 [45] which can break through the limitation defined by MacNeal [6, 7], a new 3D 8-node hexahedral element US-ATFH8 is constructed by employing the unsymmetric element method, the analytical trial function method and the oblique coordinate method. This new 3D low-order element, which can be treated as an extension from the plane element US-ATFQ4, possesses following advantages superior to most existing 8-node hexahedral element models:
(i) Its formulations contain no adjustable factor, and can be used for both isotropic and anisotropic cases;

(ii) It can strictly pass both the first-order (constant stress/strain) patch test and the second-order patch test for pure bending (free of trapezoidal locking), which cannot be achieved by most other existing finite element models;

(iii) It is free of volume locking, and provides the invariance for coordinate rotation;

(iv) It is insensitive to various mesh distortions, and can produce stable and better solutions for higher-order problems (the orders of the displacement fields are higher than first- and second-order).

The appearance of above new low-order elements with high accuracy and distortion resistance may open a way for establishing new finite element system which can relax the requirements for hexahedron mesh generation. This point may have great significance for further development of the finite element method. Although the element stiffness matrix is unsymmetric, it is not a serious issue in most of the problems in structural analyses: many solvers can handle this situation easily [1, 58].

Of course, before this new model can be really applied in practical engineering, many further technique problems must be solved. Whether the present method can be extended to the applications of shell and nonlinear problems is still a valuable and challenging research topic that should be paid attention to. Some related developments will be reported in near future.

APPENDIX A: NINE SETS OF ANALYTICAL GENERAL SOLUTIONS FOR GLOBAL LINEAR STRESSES, STRAINS AND QUADRATIC DISPLACEMENTS IN TERMS OF $R, S$ AND $T$

Let
\[ h_1 = b_2 \tilde{c}_3 + b_3 \tilde{c}_2, \quad h_2 = a_3 \tilde{c}_3 + a_3 \tilde{c}_2, \quad h_3 = a_3 b_3 + a_3 b_2 \\
\[ h_4 = b_3 \tilde{c}_3 + b_3 \tilde{c}_1, \quad h_5 = a_3 \tilde{c}_3 + a_3 \tilde{c}_1, \quad h_6 = a_3 b_3 + a_3 b_1 \]
\[ h_7 = b_1 \tilde{c}_2 + b_2 \tilde{c}_1, \quad h_8 = a_2 \tilde{c}_2 + a_2 \tilde{c}_1, \quad h_9 = a_2 b_2 + a_2 \tilde{b}_1 \]

Then, from Equations (11) to (14), the resulting solutions for global linear stresses, strains and quadratic

\[ \text{displacements can be written as follows.} \]

1. \textit{Nine sets of analytical general solutions for global linear stresses and strains in terms of } R, S \text{ and } T

(1) The 13th set of solutions for global stresses and strains

\[ \sigma_{x13} = \tilde{a}_2^2 R, \quad \sigma_{y13} = \tilde{b}_2^2 R, \quad \sigma_{z13} = \tilde{c}_2^2 R, \quad \tau_{x13} = \tilde{a}_2 b_2 R, \quad \tau_{y13} = \tilde{b}_2 c_2 R, \quad \tau_{z13} = \tilde{c}_2 c_2 R; \]  

(2) The 14th set of solutions for global stresses and strains

\[ \sigma_{x14} = \tilde{a}_3^2 R, \quad \sigma_{y14} = \tilde{b}_3^2 R, \quad \sigma_{z14} = \tilde{c}_3^2 R, \quad \tau_{x14} = \tilde{a}_3 b_3 R, \quad \tau_{y14} = \tilde{b}_3 c_3 R, \quad \tau_{z14} = \tilde{c}_3 c_3 R; \]
Strains:

for isotropic case

\[
\begin{align*}
\varepsilon_{x14} &= \frac{1}{E}(\varepsilon_x^3 - \mu\varepsilon_x^3 - \mu\varepsilon_y^3)R = A_{x14}R, \\
\varepsilon_{z14} &= \frac{1}{E}(\varepsilon_z^3 - \mu\varepsilon_z^3 - \mu\varepsilon_y^3)R = A_{z14}R, \\
\gamma_{yz14} &= \frac{2(1 + \mu)}{E}b_y\varepsilon_z R = A_{yz14}R, \\
\gamma_{zx14} &= \frac{2(1 + \mu)}{E}b_x\varepsilon_z R = A_{zx14}R
\end{align*}
\]

for anisotropic case

\[
\begin{align*}
\varepsilon_{x14} &= (\varepsilon_x^3 C_{11} + \varepsilon_y^3 C_{12} + \varepsilon_z^3 C_{13} + \varepsilon_x^2 b_y C_{11} + \varepsilon_z^2 c_y C_{13} + \varepsilon_x^2 C_{14} + \varepsilon_z^2 C_{15} + \varepsilon_x^2 C_{16})R = A_{x14}R \\
\varepsilon_{y14} &= (\varepsilon_y^3 C_{21} + \varepsilon_y^3 C_{22} + \varepsilon_z^3 C_{23} + \varepsilon_y^2 b_y C_{21} + \varepsilon_z^2 C_{24} + \varepsilon_y^2 C_{25} + \varepsilon_z^2 C_{26})R = A_{y14}R \\
\varepsilon_{z14} &= (\varepsilon_z^3 C_{31} + \varepsilon_y^3 C_{32} + \varepsilon_z^3 C_{33} + \varepsilon_y^2 b_y C_{34} + \varepsilon_z^2 C_{35} + \varepsilon_y^2 C_{36})R = A_{z14}R \\
\gamma_{yz14} &= (\varepsilon_y^2 C_{41} + \varepsilon_y^2 C_{42} + \varepsilon_z^2 C_{43} + \varepsilon_y^2 b_y C_{44} + \varepsilon_z^2 C_{45} + \varepsilon_y^2 C_{46})R = A_{yz14}R \\
\gamma_{zx14} &= (\varepsilon_z^2 C_{51} + \varepsilon_y^2 C_{52} + \varepsilon_z^2 C_{53} + \varepsilon_z b_y C_{54} + \varepsilon_z C_{55} + \varepsilon_y C_{56})R = A_{zx14}R \\
\gamma_{xz14} &= (\varepsilon_z^2 C_{61} + \varepsilon_y^2 C_{62} + \varepsilon_z^2 C_{63} + \varepsilon_z b_y C_{64} + \varepsilon_z C_{65} + \varepsilon_y C_{66})R = A_{xz14}R
\end{align*}
\]

(3) The 15th set of solutions for global stresses and strains

\[
\sigma_{x15} = 2\alpha_2\alpha_3 R, \quad \sigma_{y15} = 2\alpha_2\beta_3 R, \quad \sigma_{z15} = 2\beta_2\beta_3 R, \quad \tau_{y15} = h_3 R, \quad \tau_{z15} = h_1 R, \quad \tau_{x15} = h_2 R; \quad (A6)
\]

Strains:

for isotropic case

\[
\begin{align*}
\varepsilon_{x15} &= \frac{2}{E}(\alpha_2\alpha_3 - \mu\beta_3\beta_4 - \mu\beta_2\beta_3)R = A_{x15}R, \\
\varepsilon_{z15} &= \frac{2}{E}(\beta_2\beta_3 - \mu\alpha_2\alpha_3 - \mu\alpha_2\alpha_3)R = A_{z15}R, \\
\gamma_{yz15} &= \frac{2(1 + \mu)}{E}(\beta_2\beta_3 + \alpha_2\alpha_3)R = A_{yz15}R, \\
\gamma_{zx15} &= \frac{2(1 + \mu)}{E}(\alpha_2\alpha_3 + \beta_2\beta_3)R = A_{zx15}R
\end{align*}
\]

for anisotropic case
\[
\begin{align*}
\varepsilon_{x15} &= (2\tilde{a}_2\tilde{a}_1C_{11} + 2\tilde{b}_2\tilde{b}_1C_{12} + 2\tilde{c}_2\tilde{c}_1C_{13} + h_1C_{14} + h_1C_{15} + h_1C_{16})R = A_{x15}R \\
\varepsilon_{y15} &= (2\tilde{a}_2\tilde{a}_1C_{21} + 2\tilde{b}_2\tilde{b}_1C_{22} + 2\tilde{c}_2\tilde{c}_1C_{23} + h_2C_{24} + h_2C_{25} + h_2C_{26})R = A_{y15}R \\
\varepsilon_{z15} &= (2\tilde{a}_2\tilde{a}_1C_{31} + 2\tilde{b}_2\tilde{b}_1C_{32} + 2\tilde{c}_2\tilde{c}_1C_{33} + h_3C_{34} + h_3C_{35} + h_3C_{36})R = A_{z15}R \\
\gamma_{xy15} &= (2\tilde{a}_2\tilde{a}_1C_{41} + 2\tilde{b}_2\tilde{b}_1C_{42} + 2\tilde{c}_2\tilde{c}_1C_{43} + h_4C_{44} + h_4C_{45} + h_4C_{46})R = A_{xy15}R \\
\gamma_{yz15} &= (2\tilde{a}_2\tilde{a}_1C_{51} + 2\tilde{b}_2\tilde{b}_1C_{52} + 2\tilde{c}_2\tilde{c}_1C_{53} + h_5C_{54} + h_5C_{55} + h_5C_{56})R = A_{yz15}R \\
\gamma_{xz15} &= (2\tilde{a}_2\tilde{a}_1C_{61} + 2\tilde{b}_2\tilde{b}_1C_{62} + 2\tilde{c}_2\tilde{c}_1C_{63} + h_6C_{64} + h_6C_{65} + h_6C_{66})R = A_{xz15}R
\end{align*}
\] (A7b)

(4) The 16th set of solutions for global stresses and strains

Stresses:

\[
\sigma_{x16} = \tilde{a}_1^2S, \quad \sigma_{y16} = \tilde{b}_1^2S, \quad \sigma_{z16} = \tilde{c}_1^2S, \quad \tau_{xy16} = \tilde{a}_1\tilde{b}_1S, \quad \tau_{yz16} = \tilde{a}_1\tilde{c}_1S, \quad \tau_{xz16} = \tilde{a}_1\tilde{c}_1S; \quad (A8)
\]

Strains:

for isotropic case

\[
\begin{align*}
\varepsilon_{x16} &= \frac{1}{E}(\tilde{a}_1^2 - \mu\tilde{b}_1^2 - \mu\tilde{c}_1^2)S = A_{x16}S, \quad \varepsilon_{y16} = \frac{1}{E}(\tilde{b}_1^2 - \mu\tilde{a}_1^2 - \mu\tilde{c}_1^2)S = A_{y16}S \\
\varepsilon_{z16} &= \frac{1}{E}(\tilde{c}_1^2 - \mu\tilde{a}_1^2 - \mu\tilde{b}_1^2)S = A_{z16}S, \quad \gamma_{xy16} = \frac{2(1 + \mu)}{E}\tilde{a}_1\tilde{b}_1S = A_{xy16}S \\
\gamma_{yz16} &= \frac{2(1 + \mu)}{E}\tilde{a}_1\tilde{c}_1S = A_{yz16}S, \quad \gamma_{xz16} = \frac{2(1 + \mu)}{E}\tilde{a}_1\tilde{c}_1S = A_{xz16}S
\end{align*}
\] (A9a)

for anisotropic case

\[
\begin{align*}
