Key words
Inflammation; pattern recognition receptors; viral; hierarchical clustering, reproductive immunology

Abbreviations:
ECS, elective caesarean section; HMW, high molecular weight; IL-, interleukin; LMW, low molecular weight; PAMPs, pathogen associated molecular patterns; PRR, pattern recognition receptor; PTB, preterm birth; RIG-I, retinoic acid inducible gene I; RLR, RIG-I-like receptor; TLR, toll-like receptor.
Abstract

The role of viral infections in adverse pregnancy outcomes has gained interest in recent years. Innate immune pattern recognition receptors (PRRs) and their signalling pathways that yield a cytokine output in response to pathogenic stimuli have been postulated to link infection at the maternal-fetal interface and adverse pregnancy outcomes. The objective of this study was to investigate the expression and functional response of nucleic acid ligand responsive Toll-like receptors (TLR3, 7, 8 and 9), and retinoic acid-inducible gene 1 (RIG-I)-like receptors (RIG-I, MDA5 and LGP2) in human term gestation-associated tissues (placenta, choriodecidua and amnion) using an explant model. Immunohistochemistry revealed that these PRRs were expressed by the term placenta, choriodecidua and amnion. A statistically significant increase in interleukin (IL)-6 and/or IL-8 production in response to specific agonists for TLR3 (Poly(I:C); low and high molecular weight), TLR7 (Imiquimod), TLR8 (ssRNA40) and RIG-I/MDA5 (Poly(I:C)LyoVec) was observed; there was no response to a TLR9 (ODN21798) agonist. A hierarchical clustering approach was used to compare the response of each tissue type to the ligands studied and revealed that the placenta and choriodecidua generate a more similar IL-8 response, while the choriodecidua and amnion generate a more similar IL-6 response to nucleic acid ligands. These findings demonstrate that responsiveness via TLR3, TLR7, TLR8 and RIG-I/MDA5 is a broad feature of human term gestation-associated tissues with differential responses by tissue that might underpin adverse obstetric outcomes.
Introduction

Cytokine production at the materno-fetal interface is a part of normal pregnancy and the changes that occur with adverse obstetric outcomes might offer therapeutic targets. The relationship between bacterial infection and preterm rupture of the membranes (PROM) and preterm birth (PTB) has been given much attention but recent years have seen the emergence of epidemiological evidence linking viral infection and adverse pregnancy. These viral infections include human papillomavirus, hepatitis virus, herpes virus and cytomegalovirus which have been identified in both gestational tissues and amniotic fluid, and linked to increased risk of chorioamnionitis and spontaneous preterm birth. Therefore, better understanding of the response of gestation-associated tissues to viruses is required.

Pattern recognition receptors (PRRs) are evolutionary conserved germline encoded receptors which recognise pathogen associated molecular patterns (PAMPs) from various microorganisms. Recognition of viral infections by the innate immune response occurs via nucleic acid responsive toll-like receptors (TLRs) 3, 7, 8 and 9, and retinoic acid-inducible gene (RIG)-1-like receptors (RLRs) RIG-I, MDA5 and LGP2. These receptors are located intracellularly where they are best positioned to encounter and respond to viruses. Better understanding of the expression and function of viral responsive PRRs at the materno-fetal interface is required for our fundamental understanding of pregnancy immunology and for translating this to the development of new therapeutic approaches for adverse obstetric outcomes. There are no published studies of RLR expression in gestation-associated tissues. For TLRs 3, 7, 8 and 9 only the placenta has been investigated with transcripts and/or protein for all of these reported with functional responses observed to TLR3, TLR7 and TLR7/8 but not TLR9 agonists. Therefore, we investigated the expression and activity of nucleic acid ligand responsive TLRs (TLR3, 7, 8 and 9) and RLRs (RIG-I, MDA5 and LGP2) in human term placenta, choriodecidua and amnion using an explant model to better mimic the cellular heterogeneity that occurs in utero. A hierarchical clustering approach, as previously described for cytokine data, was implemented to better compare the response between
different tissues and ligands. It is our hypothesis nucleic acid ligands will induce an inflammatory response in gestation associated tissues and that utilisation of hierarchical clustering to examine cytokine production by the placenta, choriodecidua and amnion in response to these PAMPs will highlight distinct differences in their responsiveness not revealed in previous studies.
Materials and Methods

Samples

Placenta and fetal membrane samples were collected from healthy term newborns (>37 weeks of gestation) delivered by ECS at Singleton Hospital, Swansea, UK. Written consent was obtained from all study participants following recruitment at the antenatal day assessment unit. Ethical approval for this study was given by Wales Research Ethics Committee 6 (REC No. 11/WA/0040).

Explant Cultures

Placenta. Placental explant cultures were prepared as described previously . The decidua basalis overlaying the maternal side of the placenta was removed and 1 cm³ pieces of placental tissue were extracted from various sites across the placenta, avoiding the fetal membranes, and placed into sterile calcium and magnesium free phosphate buffered saline (PBS; Life Technologies, UK). Tissue was washed repeatedly with PBS to remove contaminating blood. Tissue was then minced into smaller pieces and washed further. Pieces of tissue (1 mm³ pieces to a total of 0.2 g) were transferred into the appropriate number of wells of a standard 12-well tissue culture plate (Greiner Bio-one, Germany) containing 1 ml UltraCULTURE™ medium (Lonza, Switzerland), supplemented with 2 mM GlutaMAX™ (Life Technologies, UK) and 2 mM penicillin, streptomycin, fungisone (PSF; Life Technologies, UK).

Membranes. Membranes were detached from the placenta. Choriodecidua and amnion were separated from each other by blunt dissection and placed individually and washed repeatedly in sterile Ca²⁺/Mg²⁺ free phosphate buffered saline (PBS; Life Technologies) to remove blood. Explants were cut with an 8-mm biopsy punch (Stiefel): two discs of choriodecidua placed into 0.5 ml Advanced RPMI supplemented with 2 mM Glutamax, 2 mM Penicillin streptomycin fungizone (PSF), 5 mM 2-mercaptoethanol (2-ME; all Life Technologies) and 2% fetal bovine serum (FBS; Hyclone) and 5 mM 2-mercaptoethanol; and four discs of
amnion placed into 0.5 ml Advanced DMEM (Life Technologies) supplemented with 2mM Glutamax, 2mM PSF and 2% FBS.

Explant cultures were exposed to different stimuli; an unstimulated control was always included. Optimal levels of all agonists were determined by dose course studies on gestation-associated tissues explants and the following final concentrations were used: Poly(I:C)LMW (TLR3, 25 μg/ml), Poly(I:C)HMW (TLR3, 25 μg/ml), Imiquimod (TLR7, 1 μg/ml) ssRNA40 (TLR8, 1 μg/ml), Poly(I:C)LyoVec (RIG-I/MDA5, 1 μg/ml) (all from Invivogen, USA), ODN21798 control or ODN21798 (TLR9, 1 μM; both Miltenyi Biotec, UK). All treatments were performed in duplicate. Cultures were incubated for 24 hours at 37°C in 5% CO₂. Tissue free supernatants were collected by centrifugation for 7 minutes at 4°C, 515 x g and stored at -20°C for analysis using cytokine specific ELISAs.

**Cytokine production**

IL-6 and IL-8 in the tissue free supernatants of placenta, choriodecidua and amnion explant cultures collected after 24 h were measured using commercially available ELISA kits (DuoSet, R&D Systems) as per manufacturer’s instructions.

**Immunohistochemistry**

Immunohistochemistry was performed on formalin fixed, paraffin embedded sections (4 μm) of placenta and fetal membranes using the Ventana ULTRA automated staining instrument. The Optiview detection system was used without A/B blocker or amplification (except for anti-TLR9). Antigen retrieval was carried out in CC132 buffer for TLR3, RIG-I and MDA5 and CC124 buffer for TLR7, TLR8 and LGP2. Primary antibodies, rabbit polyclonal anti-TLR3 (5 μg/ml for 24 minutes), rabbit polyclonal anti-TLR7 (10 μg/ml for 36 minutes), rabbit polyclonal anti-TLR8 (5 μg/ml for 32 minutes), rabbit polyclonal anti-TLR9 (10 μg/ml for 44 minutes), rabbit polyclonal anti-RIG-I (10 μg/ml for 32 minutes), rabbit polyclonal anti-MDA5 (5 μg/ml for 36 minutes), and rabbit polyclonal anti-LGP2 (5 μg/ml
for 36 minutes) (all LifeSpan BioSciences, Inc, USA) were incubated at 36°C or, for anti- TLR8, at room temperature. For control slides, primary antibody was replaced with polyclonal rabbit IgG (Biolegend) at a corresponding concentration. A tissue reported to express the receptor of interest was used for optimisation of staining and included as a positive control: tonsil (TLR3, TLR8, RIG-1, MDA5, LGP2), lung (TLR7), liver (TLR9).

Data analysis
All experiments were performed a minimum of three times. Cytokine production in untreated versus treated tissue was evaluated by paired two-tailed Student t-test or repeated measures one-way ANOVA with Dunnett’s multiple comparison test. A p-value of ≤ 0.05 was considered significant. Statistical significance was calculated using GraphPad Prism (Version 6, GraphPad Software Inc, USA). Heatmaps were constructed for each cytokine using the mean values generated by ELISA, corrected for baseline constitutive levels, with the 'heatmap.2' function in the 'gplots' R package. Hierarchical clustering was performed using a 'euclidean' distance method.
Results

Localization of TLR3, TLR7, TLR8 and TLR9 in human non-laboured gestation associated tissues

Immunohistochemistry was used to determine which cells within the placenta and fetal membranes expressed TLR3, 7, 8 and 9 (Figure 1). In the placenta, expression of all four TLRs by trophoblast was a common feature with strong expression for both TLR3 and TLR8 in the trophoblast and villous stromal cells. In the fetal membranes, amnion epithelial cells, chorionic trophoblasts and decidual cells all exhibited strong expression of TLR3 and TLR8. Expression of TLR7 was primarily localised to the chorion with weak staining in the amnion. Intermittent expression of TLR9 was also observed.

Functional response of term non-laboured gestation associated tissue to specific TLR3 TLR7, TLR8 and TLR9 agonists

TLR3. Functionality of TLR3, a receptor involved in the recognition of dsRNA, was investigated using a synthetic dsRNA analogue Poly(I:C) (Polyinosine-polycytidylic acid; both 25 µg/ml, n=9). Both a high molecular weight (HMW, 1.5-8kb) and a low molecular weight (LMW, 0.2-1kb) version of the poly(I:C) were utilised based on reports of differences in activation efficacy determined by molecular weight 16. For the placenta and amnion, IL-8 production was elevated significantly upon stimulation with both LMW and HMW Poly(I:C) whereas IL-6 was only elevated significantly upon stimulation with LWM Poly(I:C). For the choriodecidua HMW and LMW Poly(I:C) resulted in a significant increase of both IL-6 and IL-8 (Figure 2). HMW poly(I:C) gave a greater cytokine response than LMW poly(I:C) which was significant in all cases except for IL-6 production in the amnion.
TLR7 and TLR8. TLR7 and TLR8 functionality were studied using imiquimod (R837) and ssRNA40/LyoVec each at 1 µg/ml (Figure 3; n=9). Imiquimod is small synthetic antiviral molecule in the imidazoquinoline family specific to TLR7, while ssRNA40/LyoVec, is a single stranded uridine-rich oligonucleotide derived from HIV-1 complexed with the transfection reagent LyoVec and is specific for TLR8 17,18. The TLR8 agonist ssRNA40 caused an increase in IL-6 and IL-8 in placenta, choriodecidua and amnion which was significant in all cases except for IL-8 in the amnion (Figure 3). In contrast, the TLR7 agonist imiquimod induced a significant increase in IL-8 from all three tissues but only from the amnion for IL-6 (Figure 3).

TLR9. The function of TLR9 was investigated using a synthetic P-class oligodeoxyribonucleotide containing unmethylated CpG motifs (ODN 221798) at 1 µM (Figure 4; n=7). A sequence control was also included. There was no significant effect of ODN221798 on either cytokine in any tissue.

Localization of RIG-I, MDA5 and LGP2 in human non-laboured gestation associated tissues

Immunohistochemistry was used to determine which cells within the placenta and fetal membranes expressed RIG-I, MDA5 and LGP2 (Figure 5). In the placenta, trophoblasts showed strong expression of all three RLRs with expression of MDA5 and LGP2 also in the villous stroma. In the fetal membranes, expression of RIG-I, MDA5 and LGP2 was observed on chorionic trophoblasts, decidual cells and amnion epithelial cells.

Functional response of term non-laboured gestation associated tissue to a RIG-I/MDA5 agonist

RIG-I/MDA5 functionality was determined using Poly(I:C)/LyoVec, a complex between the transfection reagent LyoVec and HMW poly(I:C) at 1 µg/ml (Figure 6; n =9). Transfected Poly(I:C) is recognised by RIG-I/MDA5 unlike naked Poly(I:C) which is recognised by
TLR3 \(^{19,20}\). In all three tissues a significant increase in both IL-6 and IL-8 was observed in response to Poly(I:C)LYOVec.

Hierarchical clustering of the response to nucleic acid sensing TLRs/RLRs

Heatmaps were drawn to better visualise and enable a comparison of the cytokine response by each of the tissues and each of the ligands (Figure 7). Each row represents a tissue and each column represents a ligand with light grey representing high production levels and dark grey/black low. Hierarchical clustering of the three tissues revealed that for IL-6 production the choriodecidua and amnion clustered together compared to the placenta whereas for IL-8 production the placenta and choriodecidua clustered together compared to the amnion. When examining the response of the tissues to treatment with nucleic acid PAMPs two primary clusters for each cytokine were evident. For IL-6, the response of TLR3 activation by LMW poly(I:C) clustered with TLR8, independent of the TLR3/HMW poly(I:C), TLR7 and RIG-I/MDA5. For IL-8, the response to TLR7/8 activation clustered independently of TLR3 (both LMW and HMW Poly(I:C)) and RIG-I/MDA5.
Discussion

This study reports for the first-time expression and function of RLRs by the placenta, choriodecidua and amnion. Additionally, we note distinct differences in TLR3, TLR7 and TLR8 function in these tissues compared to previous studies relating to the different agonists used. Furthermore, we provide a novel comparison of the cytokine producing capacity of the placenta, choriodecidua and amnion in response to nucleic acids.

Protein expression of TLRs 3, 7, 8 and 9 was observed within placental trophoblast, amnion epithelium, chorionic trophoblasts and the decidua. There was variability in expression: most notably TLR9 showed lowest levels of staining and TLR7 expression was negligible within the decidua. Immunoreactivity of TLR3, 7 and 8 has been reported previously in placental syncytiotrophoblasts and cytotrophoblasts of both normotensive and preeclampsia placentas. Our findings confirm this and extend this observation to the fetal membranes where immunoreactivity was also found. Broadly, patterns of immunoreactivity corresponded to the functional output apart from TLR9 where no functional output was observed.

While a functional response to the TLR3 ligand poly(I:C) has been observed in both placental and fetal membrane explants, the efficiency of TLR3 activation has been reported to be influenced by the size of the dsRNA used. Here we note TLR3 activation by LMW poly(I:C) induced a higher cytokine response than HMW poly(I:C) possibly due to better penetration into the cell of smaller RNAs. This highlights the importance of considering the size of poly(I:C) used when examining TLR3 function in gestational tissues, possibly offering an explanation for why no IL-8 production was observed in fetal membrane explants following poly(I:C) treatment.

While TLR7 and TLR8 are phylogenetically related and both recognise ssRNAs, the cytokine response resulting from activation of TLR8 by both the placenta and fetal membranes is more robust than that of TLR7 apart from IL-8 production by the amnion. This
might be related to the greater expression of TLR8 than TLR7 revealed by our immunohistochemical analysis. Previous functional investigations of TLR7 and TLR8 in gestational tissues have typically utilised dual synthetic agonists or ssRNAs \(^6,12\), noting both IL-6 and IL-8 production by the placenta \(^12\) and IL-8 production by the fetal membranes \(^6\) in response to treatment. These discrepancies likely reflect the model of investigation used, i.e. total fetal membrane explants \(^6\) versus explants of choriodecidua and amnion as here. Tissue processing for ex vivo investigations can impact on cytokine measurements with punch biopsies of amnion or choriodecidua, as used here, typically making greater amounts of cytokines than dual compartment transwells \(^23\). Furthermore, the activation of TLR7 and TLR8 by synthetic agonists results in differences in target cell selectivity and cytokine profile \(^24\).

We have previously reported that the human term placenta does not elicit either pro-inflammatory (IL-6, IL-8 and TNFα) or anti-inflammatory (IL-10) cytokines in response to an A-class CpG ODN \(^12\). However, several classes (A, B, C and P) of CpG ODN are available with C-class combining features of A-class and B-class, while P-class activates at a higher efficiency than C-class \(^25,26\). Therefore, we chose to use a P-class ODN for this study. Again, we report no functional response by any tissues to P-class CpG ODN despite TLR9 immunoreactivity within placental trophoblasts and, more weakly, in various cells of the fetal membranes. To the best of our knowledge this is the first report of TLR9 protein localisation in the placenta and fetal membranes. Limited expression of TLR9 might offer an explanation as to why no functional response to CpG was observed corresponding to observations of expression versus function in monocytes and natural killer cells \(^27\). However, measurement of a wider array of cytokines/chemokines could reveal TLR9 functionality. Increased MCP-1 and decreased G-CSF, IFNγ, MIP-1α, MIP-1β, RANTES and VEGF in response to Class-A CpG ODN by human fetal membrane explants has been reported \(^28\). However, it is likely that TLR9 activity at the materno-fetal interface is tightly regulated rather than non-functional to minimise placental inflammation from endogenous signals.
Hypomethylated fetal DNA, found in the placenta and maternal circulation with circulating levels increased in preeclampsia, can activate TLR9 signalling in human peripheral blood mononuclear cells (PBMCs) in vitro with elevated IL-6 production. Placental derived mitochondrial DNA is associated with TLR9 activation and vascular dysfunction in preeclampsia and TLR9 expression is elevated on circulating plasmacytoid dendritic cells (pDCs) of preeclamptic versus healthy pregnant women and is accompanied by a lesser cytokine output in response to TLR9 activation.

The cytoplasmic RNA helicases of the RLR family play a major role in host anti-viral defence. They detect viral RNA ligands in the cytoplasm, triggering activation of transcription factors and leading to production of type I IFNs and expression of other anti-viral genes. Our knowledge of RLR expression and function in human gestation associates tissues is relatively limited. Here we demonstrate for the first-time immunoreactivity for RIG-I, MDA5 and LGP2 in the placenta and fetal membranes. Both RIG-I and MDA5 were localised to the placental trophoblasts, chorionic trophoblasts, decidual stromal cells and amnion epithelial cells. A corresponding functional output was observed with the dual agonist for these receptors. Further work is required to determine the relative contribution of RIG-I and MDA5 to this response. Recognition of dsRNAs by RIG-I and MDA5 is reported to be length dependent. As RIG-I selectively recognises short dsRNA and MDA5 long, given HMW dsRNA was used in our study the response is most likely MDA5-dependent but further work is required to confirm this. LGP2 shared its expression pattern with RIG-I and MDA5. This is not surprising given that LGP2 is a negative regulator of RLR signalling. This negative feedback takes place on many levels including competition for dsRNA, interaction with the adaptor molecule ISP-1, or direct binding of RIG-I.

Our investigation of the responsiveness of gestation-associated tissues to nucleic acid PRRs, namely TLR3, 7, 8 and 9, and RIG-I and MDA5 provides further insight into inflammatory
responses at the materno-fetal interface. Protein expression of these PRRs and LGP2 was a broad feature of human term gestation-associated tissues yet there were subtle differences in functional responses. Hierarchical clustering enabled elucidation of these key differences between tissues and treatments to be highlighted. This approach revealed that the placenta and choriodecidua respond to nucleic acid ligands more similarly than the amnion regarding the production of IL-8. IL-8 is a key chemokine in the recruitment and activation of neutrophils \(^{36}\) which have a role in anti-viral immunity \(^{37}\). Neutrophil infiltration of both the placenta and decidua occurs during bacterial infection \(^{38,39}\) and this might also be the case during viral infection. In contrast, hierarchical clustering revealed that in the regards to IL-6 production, the choriodecidua and amnion share a greater functional similarity.

The clustering approach utilised here has highlighted some key differences between tissues in relation to their responsiveness to nucleic acids PAMPs but this has limitations. This is a study of heterogeneous tissue explants so the relative numbers of responsive cells in each of the tissues will differ. This is evident by the constitutive production of both cytokines by each tissue and we have corrected all comparisons for this. However, normalisation of cytokine production to total protein content prior to baseline corrections would form the basis of future investigations. Furthermore, we have only applied this approach to the production of IL-6 and IL-8, based on the expectation that these would most likely yield responses to viral ligands \(^{40,41}\) and have been implicated in anti-viral defence \(^{42}\). While these are key cytokines in the physiology and pathophysiology of labour, other cytokines including IL-1\(\beta\), IL-10 and TNF\(\alpha\) have also been implicated (2). Therefore, an extensive examination of other pro- and anti-inflammatory cytokine perhaps after multiplex analysis would provide a more detailed insight into the inflammatory response of gestational tissues.

While the focuses of this study has been TLRs and RLRs, other nucleic acid sensing innate immune receptors have been described, namely the cytosolic DNA sensors (CDS), alternatively known as the absent in melanoma 2 (AIM2)-like receptors (ALRs) \(^{43}\). Several
CDS have been described including DAI, LRRFIPI, IFI16, DDX41, cGAS and AIM2. To date, little is known about either the expression or function of these cytosolic DNA sensors in gestational tissues apart from IFI16, which is associated with non-necroptotic programmed cell death of human trophoblasts following dsDNA exposure. Furthermore, placenta expression of IFI16 is significantly elevated in women with preeclampsia and this can be mimicked in vitro by treating placental trophoblasts with poly(dA:dT). This implicates IFI16 and possibly other CDS and the DNA sensing receptors studied herein in preeclampsia and highlights the importance of understanding the potential dysfunction of these receptors and their signalling pathways in pregnancy.

Acknowledgements
Funding for this research was provided by Health and Care Research Wales. A.H.B. contributed to design of the study, to the acquisition, analysis and interpretation of data and to drafting the article. G.E.M. contributed to the analysis and interpretation of data. L.M.S, S.S-H, L.I.B.D and R.A.S contributed to the acquisition of data. R.H.J contributed to acquisition of data and recruitment of participants/tissue samples. C.A.T contributed to the conception and design of the study, interpretation of data and revised the article. All authors gave their final approval of the version to be published. We are grateful to all the staff in the antenatal day assessment unit and on the delivery suite at Singleton Hospital Swansea for their tireless help in the collection of samples. Thank you also to all the women who agreed to the use of their placentas for this study.
