Abstract

Collaboration between industry and academia necessitates the management of entrepreneurial dynamics within ecosystem contexts. However, such partnerships perpetuate numerous challenges that, without effective management, can impact upon the ecosystem as a whole. Limited research to date has addressed the challenges affecting these university-industry partnerships and ascertained their impact upon ecosystem management. This study identifies the challenges pervading university-industry partnerships across entrepreneurial ecosystems, with a view that through an exposition of such challenges, more specific strategies could be implemented to address them. Questionnaires were distributed to key ecosystem stakeholders, requesting their perceptions of the key challenges affecting their collaborative relationships. Empirical data was analysed utilising fuzzy-set qualitative comparative analysis to deduce the configurational nature of the conditions. Results reveal mutually exclusive solutions grounded upon distinct combinations of conditions, constituting distinct pathways to ineffective ecosystem management. Theoretical and practical implications are discussed, as well as acknowledged limitations of this study and suggestions for future research.

1 Introduction

The general broadness and multidisciplinary of the ecosystem construct can be attributed to its widespread application in business and management, both theoretically and practically (Autio et al. 2018). While relevant across multiple fields, the concept of the ecosystem retains a significant relation with the field of

entrepreneurship (Audretsch and Belitski 2016). In line with the ecosystem analogy, Moore (1993) argues that while ecological elements rely upon each other in a biological ecosystem, entrepreneurial ecosystems are formulated of numerous stakeholders, coordinating and coevolving their capabilities around a new innovation. Entrepreneurial ecosystems encompass an emergent research field (Hakala et al. 2019) that is progressing rapidly (Kang et al. 2019) and gaining increasing importance in high-tech industries where open innovation commonly occurs between partners (Kraus et al. 2018a, b). Consequently, entrepreneurship literature demonstrates a growing interest in innovation-related ventures rather than more traditional measures of entrepreneurship (Cavallo et al. 2018). Ultimately, research argues that innovation systems such as ecosystems fail to exist without the presence of entrepreneurs (Hekkert et al. 2007). Hence, with extant literature emphasising a strong interrelation between innovation and entrepreneurship (Bosco et al. 2018; Ferreira et al. 2017; Roig-Tierno et al. 2018) the innovation partnerships occurring within entrepreneurial ecosystems constitute an important research area.

Ecosystems encourage institutions to interact, communicate, transfer knowledge and be creative (Bouncken et al. 2018). Industry 4.0 has stimulated a wide variety of firms to engage in entrepreneurial ecosystems (Schneider 2018) including large firms, universities, financial firms, and public organisations that support new and growing firms (Brown and Mason 2017). The diverse nature of these partners hence necessitates the investigation of the entrepreneurial ecosystem across different contexts (Autio et al. 2014). Universities adopt several roles within an ecosystem (Malecki 2018). University-industry partnerships involve collaboration between academic institutions and non-academic organisations (see Perkmann and Walsh 2007 for a more detailed exploration). Rising university-industry collaboration has led to increased innovation activity (Perkmann and Walsh 2007) which can lead to commercialisation through the creation of new ventures (Bosco et al. 2018). Theoretically this process is coined ‘academic entrepreneurship’ and comprises a burgeoning research avenue, with recent studies attempting to shed light on the conditions and factors that favour or inhibit this phenomenon (Bosco et al. 2018). However, universities can also collaborate with industry for alternative purposes. Research organisations such as universities may be at a position to provide novel knowledge formulated upon emerging research ideas (Nieto and Santamaría 2007). University-based research operates as a significant knowledge asset, facilitating more effective knowledge searches by firm researchers for the purposes of innovative developments (Chesbrough et al. 2006). Reflecting the premise of open innovation, Ivascu et al. (2016) argue that universities assist organisations in researching potential issues that cannot be solved by the organisation itself.

The significance of university-industry knowledge sharing has become increasingly necessary in recent years (Carayannis et al. 2019). Such partnership types enable firms to access differentiated knowledge (Santoro and Saporito 2006). Universities support innovation in general (Arant et al. 2019) operating as a source of new ideas, with industry offering pathways to capitalise upon such ideas (Ferreira and Carayannis 2019; Wit-de Vries et al. 2019). The multi-disciplinary research arising from university-industry partnerships is vital for solving increasingly complex social problems (Boardman and Gray 2010). Hence, university-industry partnerships

generate intangible support infrastructures and drive innovation, growth and prosperity in the wider economy. However, the circumstances under which such university-industry collaboration is successful remains unclear (Arant et al. 2019). Hence, in order to increase the likelihood of successful collaboration, key challenges need to be addressed (Bruneel et al. 2010).

Given the interrelation between universities and industry (Erina et al. 2017) existing debates focus on how entrepreneurial dynamics are governed, and which actors, such as universities, play a significant role (Cavallo et al. 2018). Resultantly, Cavallo et al. (2018) call for a common perspective on the governance mechanisms that regulate the evolutionary process of entrepreneurial ecosystems. While some studies have explored the key challenges facing entrepreneurial ecosystems (Autio and Levie 2017) explicit attention towards the dynamic challenges between universities and industry collaboration remains largely absent from extant entrepreneurial ecosystems literature. Consequently, Vasconcelos et al. (2018) call for further research on how to effectively manage challenges across an ecosystem. Correspondingly, building upon the research of Bosco et al. (2018), who identify key challenges of the academic entrepreneurial process, this study ascertains the challenges of the relationships between industry and academia within entrepreneurial ecosystems. Moreover, identifying how these challenges contribute to ineffective management is key. Given that extant literature cites a multitude of challenges (see Sect. 2) it becomes unlikely that a single challenge pervades all partnerships; indeed, in a practical sense, partnership issues rarely originate from a single factor. They are more likely to originate from a complex myriad of conditions, thus making fsQCA an apt analytical tool for analysing the combinations of conditions that lead to ineffective ecosystem management. Due to the significant relationship between university and industry in ecosystem contexts (Malecki 2018) identifying how these partnerships are managed and what barriers need to be overcome to ensure effective management becomes crucial and remains an area of research that is largely absent from extant ecosystems literature.

This study remedies this absence by making the following contributions. Firstly, ecosystem partnerships often exhibit high failure rates (Lauritzen and Karafyllia 2019). This study offers a novel contribution to the entrepreneurial ecosystems literature through identifying the conditions that lead to ineffective ecosystem management. This leads to potential explanations of why ecosystem partnerships fail, an important implication for practitioners who could resultantly attribute partnership failure to specific factors that may exist in their partnerships. Second, while research has begun to provide greater insights into the key challenges affecting entrepreneurial ecosystems (Bosco et al. 2018) further work is needed to ascertain the configurational nature of these conditions. This study extends previous research examining different ecosystems through an entrepreneurial lens (Theodoraki and Messeghem 2017) utilising fsQCA to detect how conditions combine into configurational recipes, revealing that all conditions are sufficient for ineffective ecosystem management, but not necessary. This study hence contributes to the ecosystems literature through evidencing the interconnected causal relations between the conditions, and their combinations into multiple solutions, which further elucidates how ineffective ecosystem management occurs. This offers important insights for

practitioners, revealing that often, ineffective ecosystem management does not arise due to independent, isolated factors posing a challenge, but instead multiple conditions that occupy core and peripheral positions. In addition, with extant entrepreneurial ecosystems research primarily conducted in the US (Kang et al. 2019; Liguori et al. 2019) this study offers a geographically distinct analysis through utilising a UK-based sample. Finally, with existing studies demonstrating a preference towards comparative methodologies (Arruda et al. 2014; Manolova et al. 2017; Voelker 2012) this study utilises fuzzy-set Qualitative Comparative Analysis (fsQCA) to identify causal configurations of key challenges that contribute to ineffective ecosystem management, contributing to the rising application of configurational techniques in innovation-related disciplines (Kraus et al. 2018a, b) and entrepreneurship (Zardini et al. 2020). Identifying the interrelations between ecosystem challenges can assist practitioners in recognising the patterns of conditions that contribute to ineffective ecosystem management, facilitating an increased understanding of how to better manage their ecosystem partnerships.

The remainder of this paper is structured as follows. Section 2 outlines the research literature pertaining to university-industry partnerships across entrepreneurial ecosystems. Section 3 presents the methodology for this study. Results arising from fsQCA are provided in Sect. 4, with a discussion explored in Sect. 5. Finally, key conclusions, alongside theoretical and practical implications, and limitations of this research are provided in Sect. 6.

2 Literature review

2.1 University-industry links in entrepreneurial ecosystems

We conducted a narrative review of the ecosystem literature to provide a general discussion of university-industry partnerships in ecosystem contexts. Utilising major research databases such as EBSCO, Scopus, Emerald, and Web of Science, key terminology such as ‘entrepreneurial ecosystem’ and ‘university-industry’ was inputted into the search engines.

Entrepreneurial ecosystems emphasise interdependence between actors and factors, viewing entrepreneurship as an output of the ecosystem (Acs et al. 2017). Universities significantly contribute to entrepreneurship (Breznitz and Zhang 2019). Existing research has utilised case studies to explore how universities have established entrepreneurial ecosystems, such as highlighting the ways in which academics engage in the entrepreneurship process (Lahikainen et al. 2019) exploring the role of technology transfer offices in developing an entrepreneurial ecosystem (Schaeffer and Matt 2016) or elucidating how campuses operate as ecosystems themselves (Miller and Acs 2017). Breznitz and Zhang (2019) further elucidate the role of the university in the entrepreneurial ecosystem through examining how a university operates as an accelerator for student start-ups. Brito (2018) applied a case study methodology to examine the central role of universities within their innovation ecosystem, finding that universities act as leaders and integrators. Measuring the converse relationship, Nicholls-Nixon et al. (2020) explore the role of the

entrepreneurial ecosystem in shaping the development of university-based incubators. Hayter (2016) finds that social networks of faculty and graduate entrepreneurs drive the growth of university entrepreneurial ecosystems. Meng et al. (2019) evidence how knowledge transfer from the direction of university to industry evolves across different phases of academic entrepreneurship within an ecosystem.

While universities can collaborate with industry to form entrepreneurial ecosystems, such partnerships can also be present in wider ecosystem infrastructures, such as quadruple-helix ecosystems (Carayannis and Campbell 2009). In exploration of the knowledge transfer process, Miller et al. (2016) studied knowledge transfer factors across quadruple helix ecosystems, applying an absorptive-capacity lens: they found factors affect both the effectiveness and ability of stakeholders to engage in knowledge transfer. Bacon et al. (2019a, b) examine university-industry knowledge transfer enablers, confirming their configurational nature for a successful transfer process.

2.2 Ecosystem challenges

While these preliminary insights provide important implications for university-industry ecosystem partnerships, limited research has explored the challenges pervading these relationships in ecosystem contexts, and how they are overcome (Al-Tabbaa and Ankrah 2016). Entrepreneurs are faced with the challenge of coordinating networks of actors for numerous developments that occur in the presence of multiple uncertainties (Vasconcelos et al. 2018). As ecosystems rely upon multiple people, processes, and tools in order to operate effectively, it is perhaps unsurprising that multiple challenges can arise. Hakala et al. (2019) argue that these elements are less effective as economic agents when operating in isolation: the interaction between them determines the success of the ecosystem. Lakitan (2013) stresses that university-industry partnerships can experience numerous challenges, including low technological demand, unintensive communication, and limited adoption of innovations. Moreover, Lakitan (2013) argues that for university-industry ecosystem partnerships, 'Ivory Tower Syndrome' can still present an issue, whereby potential partners are discouraged from initiating a partnership due to universities being disconnected from everyday norms and practices. When engaging in new ventures, Lubik et al. (2013) state ecosystems are faced with numerous challenges including that the need for process innovations, need for complementary innovations, resource demands and long development times require managing complex constellations of actors to achieve successful commercialization. The impact of these challenges on effective ecosystem management becomes greater when removing them relies upon individual as well as collective efforts (West 2014).

3 Research propositions

Existing literature cites a multitude of challenges as affecting university-industry partnerships, including firm innovativeness (Howells et al. 2012; Laursen and Salter 2004) partnership expectations (Cheng and Fu 2013; Santoro and Saporito 2006; Steinmo and Rasmussen 2018) and relational risk (Fulop and Couchman 2006; Perkmann et al. 2011; Radziwon and Bogers 2019). Limited empirical research explores these challenges in the context of university-industry *ecosystem* partnerships and analyses how different configurations of these challenges may impact upon ecosystem management. Thus, to contribute towards a more coherent understanding of the configurational nature of these conditions, this study employs fsQCA to identify the complex causal interrelations between the conditions.

FsQCA is grounded upon the notion of equifinality, which purports that multiple, mutually exclusive solutions are likely to contribute to an outcome (Fiss 2011). Given that multiple conditions are cited within the extant research literature, it is unlikely that a single condition will retain overall responsibility for contributing to ineffective ecosystem management. Conditions are hence likely to combine configurationally as a component of any solution, constituting distinct pathways to ineffective ecosystem management. Thus, the following propositions are outlined:

Proposition 1 *Multiple, mutually exclusive solutions contribute to ineffective ecosystem management.*

Proposition 2 *No single condition retains overall responsibility for ineffective ecosystem management.*

3.1 Methods

3.1.1 Procedure and subjects

An initial background study was conducted to identify the key challenges pervading ecosystem partnerships. Ten individuals representing university-industry collaboration were interviewed using a semi-structured approach and were asked to discuss the challenges that commonly arose within their ecosystem partnership. Interviews were recorded and transcribed, and analysed thematically.

Based upon the challenges identified in the background study, and to confirm whether such challenges were prevalent within existing university-industry ecosystem partnerships, a questionnaire was administered to key ecosystem stakeholders. To enable compatibility with fsQCA, the questionnaires required participants to assess the extent of their agreement on a seven-point Likert scale. Statements relating to each condition were included to ascertain whether participants viewed these conditions as presenting a challenge to effective ecosystem management. For example, for mistrust, participants were asked “To what extent do you agree/disagree that a lack of trust presents a challenge to ecosystem management?” These questions

were then supplemented with additional questions encouraging participants to provide a rationale for their response, akin to Bacon et al.'s (2019a, b) study, in order to enable participants to expand upon their answers if they so wished.

As fsQCA requires an outcome measure, this study examined the extent to which the six conditions contributed to effective ecosystem management. Building upon the definition outlined by Moore (1996), this study views effective ecosystem management according to the presence of the following five components: (1) the ecosystem is effective in managing co-evolving, symbiotic, and self-reinforcing strategic contributions; (2) the ecosystem is invested in by members of the community; (3) the ecosystem progresses on the creation of end-to-end experiences of value to customers; (4) the ecosystem implements community-level governance; and (5) the ecosystem is aligned around shared intentions and a shared vision of the ecosystem future. To incorporate this measure within the questionnaires, five separate Likert-scales corresponding to each component were included. These five aspects are associated with effective ecosystem management: however, this study is investigating the extent to which the challenges contribute to ineffective ecosystem management, and hence the conditions were measured against the absence of this outcome (see Sect. 3.3).

The questionnaire was pre-tested on a sample of five participants, comprised of lay individuals who had no prior experience of ecosystem involvement, but held professional occupations. Minor revisions relating to the clarity of the questionnaire were made, with the questionnaire subsequently being distributed through online platforms. Contacts obtained through the authors' networks were invited to participate in the questionnaire, to discuss their perceptions of their university-industry partnerships residing within their ecosystem. To ascertain whether the challenges were present within existing university-industry ecosystem partnerships, participants with a wealth of experience engaging in entrepreneurial ecosystems were purposively sought. Snowball sampling was utilised to identify potentially suitable contacts who then provided details of further contacts. Participants were purposively sought according to their aptitude and experience in innovation ecosystem management: such participants were asked to provide contact details of other potentially suitable participants. Such participants were then invited to participate via email. A total of 19 complete responses were returned. Participants were either university or industry representatives, and all participants were based in the UK. Table 1 displays participant demographics.

3.2 Rationale and strengths of fsQCA

FsQCA bridges the divide between qualitative and quantitative methods. It retains some fundamental strengths of the qualitative, case-oriented approach through adopting of a view of the case as a holistic entity (Rihoux and Lobe 2009); as such, the essence of the case is not lost within the analysis, as all its interrelated components are wholly considered. Alternatively, fsQCA also implements some fundamental characteristics of quantitative approaches to data analysis. Primarily, it enables a

Table 1 Participant Demographics

Gender	Organisational position	Industry	Level of decision-making responsibility	Organisation size
Male	Initiative leader	Hospitality	Middle (tactical) level	201–500 employees

researcher to analyse multiple case studies, which is rarely achieved in traditional case-oriented research (Rihoux and Lobe 2009).

An additional justification for the application of fsQCA within this research is the relatively small number of cases (19) included within the data sample. FsQCA is frequently denoted as being of utmost suitability for small-N analyses (Kraus et al. 2018a, b), a research situation for which it was originally created (Greckhamer et al. 2008). FsQCA subsequently enables the systematic comparison of a relatively small number of cases through the inclusion of 'logical remainders' (cases without empirical evidence: see Ragin 2006).

Further, the underlying assumption of fsQCA is based upon the notion of set-relations, i.e. whether certain attributes of cases contribute to producing the outcome. As this study aimed to explore the challenges affecting ecosystem management within university-industry ecosystem partnerships, fsQCA enables this to be achieved through employing a set-theoretic research approach that illuminates whether specific challenges are subsets or supersets of ineffective ecosystem management. Finally, according to Berg-Schlusser et al. (2009), one of the original aims of QCA is to develop new theoretical arguments. FsQCA is hence employed in this study to develop new theoretical arguments surrounding the conditions that contribute to ineffective ecosystem management within university-industry partnerships.

The qualitative nature of this study meant that reliability and validity could not be assessed utilising quantitative measures. FsQCA, in being case-oriented in nature, alleviates many of the assumptions of traditional variable-oriented research (Ragin 2006). Indeed, the nature and purpose of fsQCA means that the reliability and validity of latent variables cannot be accounted for, since the technique was originally designed to be used with single item variables (Pappas et al 2019). However, fsQCA does apply the principles of Boolean algebra, where each causal combination is reduced into the simplest logically plausible recipe. This in turn increases replicability (Berg-Schlusser et al. 2009), enabling the researcher to eventually corroborate or falsify results (Rihoux and Lobe 2009).

3.3 Stages in fsQCA

The first stage in fsQCA is to calibrate the conditions. FsQCA operates on the basis of set-membership, which is defined through altering the data set such that all values possess a score between 0 and 1. Thus, the original scale measures required conversion to possess this format, necessitating specification for three threshold values: full membership, full non-membership, and the maximum level of ambiguity. Natural scale breakpoints were utilised to define set-membership, in being an accepted approach to fuzzy-set calibration (Ordanini et al. 2013; Pappas et al. 2016; Woodside 2013), with 6 being outlined as full-membership, 4.5 as a crossover point, and 3 as non-membership. The threshold for non-membership was increased to 3 to account for response bias towards the higher end of the scales. As this study was assessing the extent to which the six conditions contribute to ineffective ecosystem management, the fsQCA analysis was conducted against the absence of the outcome.

The second stage of fsQCA is to utilise set measures to generate a data matrix known as a truth table. The truth table displays the research data as a list of configurations (Rihoux and Lobe 2009). A truth table possesses 2^k rows, where k is the number of causal conditions employed within the analysis (Fiss 2011). Each row within the truth table is associated with a specific number of attributes; the truth table lists all logically possible combinations of attributes (Ragin 2006) even if there is no case data that empirically demonstrates a given combination. Having configurations without empirical instances is referred to as limited diversity (Fiss 2011): rows without cases are coined logical remainders.

In the third stage, rows within the truth table are reduced to facilitate the analysis (Fiss 2011). The first step in reducing the rows is to set a benchmark for the minimum number of cases required for a solution to be considered (Fiss 2011). Thus, a specific combination of causal attributes (i.e. one row within the truth table) may be empirically demonstrated by a certain number of cases – therefore the significance of the number of cases needs to be determined so that a threshold can be established. Within small- n analyses such as this, frequency thresholds can be set at 1. Next, the consistency of each solution needs to be assessed. Consistency refers to the degree to which solution terms and the solution as a whole are subsets of the outcome, with the minimum consistency threshold for any data set recommended as 0.75 (Ragin 2006). Cases with frequency values of less than 1 and consistency values of less than 0.75 were hence removed from the analysis. At the end of stage two, the list of rows should be reduced, to facilitate the final stage of the analysis.

Analysis of the truth table involves the examination of case distribution across the property space, and a systematic identification of those causal conditions sufficient for the outcome of interest to occur (Greckhamer et al. 2008). The analysis involves discovering combinations of conditions that are subsets or supersets of the outcome, thus arriving at sufficient or necessary conditions (Schneider and Wagemann 2012). FsQCA applies the principles of Boolean algebra to combine specific attributes into causal combinations. The combination of causal conditions will result in three solutions being produced for each analysis. Ragin (2006) summarises the three solutions. The first is a ‘complex’ solution, where no logical remainders (rows without cases) have been included. The second is a parsimonious solution, where logical remainders may be used, without any consideration of their empirical possibility. The final solution is the intermediate, which supposedly bridges the two: the intermediate solution only considers logical remainders that are plausible, where plausibility is judged using the researcher’s relevant theoretical and empirical knowledge. For this study, the parsimonious and intermediate solutions are displayed in order to deduce the core and peripheral conditions, in line with Fiss (2011).

4 Results

An initial background study was conducted to identify the main challenges pervading university-industry partnerships. Following thematic analyses of these interviews, six key challenges were identified: organisational distance, reluctance to

Table 2 fsQCA Results

innovate, relationship disorientation, mistrust, miscommunication, and relational risk. Further details regarding the background study have been excluded from this paper due to space limitations.

For fsQCA, five solutions are displayed for ineffective ecosystem management (Table 2). Solution 1 combines the absence of Mistrust, Relationship Disorientation, Organisational Distance, Miscommunication, and Reluctance to innovate, with the presence of Risk.

All conditions within this solution are peripheral: as they are only present within the intermediate solution, peripheral conditions are deemed to be less important, exchangeable, and expendable, and hence exhibiting a weaker relationship with the outcome (Fiss 2011). In practice, this can be better understood through examining which conditions are core. Solution 2 exhibits the same conditions as Solution 1, but instead Risk manifests as absent, and Reluctance to Innovate manifests as present. The absence of risk leads to the core causal configuration $\sim \text{Commfz}^* \sim \text{Riskfz}$. As this causal configuration is core, the other conditions within this solution (Mistrust, Relationship Disorientation, Organisational Distance, and Reluctance to Innovate) are peripheral, in being equally effective, whereas Miscommunication and Risk as core conditions are deemed more effective and have greater depth and significance (Fiss 2011). In other words, core-ness means effectiveness: in understanding the role of core conditions in a typology, Fiss (2011) argues that examining conditions in terms of the causal role they play within the configuration in order to produce an outcome, core elements are those that are the most important for an outcome to occur. Hence, the remainder of the solutions can be understood in these terms. We direct readers to Ragin (2006) and Fiss (2011) for greater detail on interpreting fsQCA findings. Solution 3 combines the presence of Mistrust, Relationship Disorientation, and Miscommunication, the absence of Risk, Organisational Distance, and

Reluctance to Innovate. Solution 4 exhibits the same conditions but differs on the presence of Organisational Distance in Solution 4. Finally, Solution 5 combines the presence of all conditions, with the core causal configuration Riskfz*Diffz.

No condition is present across all solutions, inferring that it is unlikely for any condition to retain necessity (Dul 2016): analyses of necessity confirmed this assumption. Overall solution coverage is high at 0.80, indicating that the five solutions account for a substantial proportion of the outcome. Overall solution consistency is high at 0.82: while a perfect consistency score of 1 has not been achieved, this score does infer that the solutions represent a relatively consistent subset of the outcome.

5 Discussion

The solutions can be grouped into three categories. The first category (Solutions 1 and 2) displays all conditions aside from Risk as absent, differing on the presence of Risk and absence of Reluctance to Innovate in Solution 1, compared to the absence of Risk and presence of Reluctance to Innovate in Solution 2. It may perhaps be the case that the presence of Innovation resulted in the core causal configuration \sim Commfz* \sim Riskfz in Solution 2. As summarised by one participant when discussing their perceptions of risk, “*the presence of human beings with differing goals, perceptions of how best to proceed and the difficulties in maintaining clear and transparent communication inherently create weak points where disagreements or misunderstandings rise to the point that they threaten the work itself*” (Participant Number 3). However, with effective communication, risk is absent. According to early research by Adner (2006), entrepreneurs must be able to navigate risk when entering an ecosystem, otherwise, such risks present a multitude of further challenges. With R&D activities purporting inherently risky activities (Radziwon and Bogers 2019) the risks are argued to be higher in university-industry partnerships (Perkmann et al. 2011). Most critical to the success of university-industry collaboration is relational risk, which includes opportunistic behaviour, a lack of commitment to the partnership, and potential spill overs (Fulop and Couchman 2006). Risks faced by universities are potentially more damaging in nature and are more difficult to manage (Fulop and Couchman 2006). FsQCA results hence confirm Perkmann, Neely and Walsh’s (2011) findings that unclear objectives are likely to incur further risk: hence, effective communication between partners is likely to mitigate that risk to an extent, explicating the causal configuration within Solution 2. Relationship disorientation and mistrust manifest as absent within this category alone, suggesting that a greater degree of orientation and trust was observed within these partnerships: as professed by one participant, “*without trust the partnership will breakdown. Trust needs to be in place to make sure the relationship is stable and to act as a safe-guard*” (Participant Number 12). Hence, a greater degree of relationship orientation and trust can be observed in this category, providing potential explanations for the absence of risk.

The second category (Solutions 3 and 4) displays the presence of Mistrust, Relationship Disorientation, and Miscommunication. With risk and innovation both

manifesting as absent, participants expressed that “*innovation carries risks and risks create so many more opportunities. Working for a large institution there is always a requirement to lower risks and just do the easiest option*” (Participant Number 9). These risks were further affected by the early emergence of these relationships. With Mistrust manifesting as present, participants stated that “*Trust takes time to build in the sector and much of the business conducted is with longstanding colleagues*” (Participant Number 14): this, alongside the presence of Relationship Disorientation, led to participants expressing that “*if [the partner is] just in it for the short run, then it is very transactional and not relational*” (Participant Number 12). These partnerships may represent new relationships that have just emerged within the ecosystem: participants expressed that “*trust takes time to build and much of [our] business conducted is with longstanding partners*” (Participant Number 5). FsQCA findings hence align with previous studies that trust is based upon established, long-standing relationships (Fang et al. 2013; Narteh, 2008; Panteli and Sockalingam, 2005). Trust is assumed to facilitate the relationship between university-industry partners (Valentín 2000) increasing knowledge transfer and reducing the negative effects of partnership differences (Steinmo and Rasmussen 2018). Resource-sharing is more likely to occur within trustworthy partnerships (Tsai 2000). Consequently, a lack of trust can result in misconceptions regarding the utility and application of knowledge (Narteh 2008): as miscommunication is also present in these solutions, it is clear that such misconceptions impacted upon the trust between partners. Hence, mistrust poses a challenge for ecosystem partners, particularly university-industry partnerships due to differences in operational practices and residence within different sectors (Masiello, Izzo and Canoro 2015).

Finally, the third category (Solution 5) interestingly displays the presence of all conditions. With Riskfz*Diffz exhibiting a core causal configuration within this category, the “*differing goals*” (Participant Number 3) possessed by ecosystem partners were found to incur further risk; participants expressed that “*we expect our partner to deliver and sometimes misalignment between ourselves and our partner can be difficult*”. Hence, organisational differences further resulted in risk in the partnership: “*continued nurturing and building of relationships to diminish any distinctions at key levels of the organizations is critical to mitigate any further risk developing*” (Participant Number 8). Existing research argues that the common differences in organisational language, culture and goals between industry and academia present a key challenge, affecting inter-organisational learning and knowledge exchange (Steinmo and Rasmussen 2018). Such differences in goals are best managed by improved communication (Plewa et al. 2013) providing support for why miscommunication is present within this solution. In support, Fulop and Couchman (2006) argue that cross-sector collaborations observed within university-industry partnerships results in a clash of cultures, making relational risk more difficult to manage. Moreover, as the presence of risk can emerge due to ‘*new partner dynamics*’ (Participant Number 11) then “*more fundamental relationship foundations mitigate communication issues*”. With mistrust present in Solution 5, strong relationship foundations are absent, allowing risk to manifest as a result.

As no condition was necessary for the outcome to occur (i.e. present in all solutions and passing 0.9 thresholds on necessity tests in fsQCA) it can be concluded

that all conditions are sufficient for the outcome to occur. Each solution constitutes a distinct pathway to the outcome, confirming equifinality and highlighting that ineffective ecosystem management occurs in multiple ways. Each solution displays distinct core and peripheral conditions, confirming that specific causal configurations are more connected with the outcome, with other conditions occupying a less 'significant' relationship. Core conditions across the solutions often manifest in causal configurations, such as $\sim \text{Commfz} * \sim \text{Riskfz}$ or $\text{Riskfz} * \text{Diffz}$, reinforcing the configurational nature of the conditions for leading to ineffective ecosystem management.

6 Conclusions

This study has provided empirical insights into the challenges pervading university-industry partnerships across entrepreneurial ecosystems. In order to examine these challenges, a questionnaire was distributed to ecosystem members to ascertain their perceptions of the challenges and their impact upon ecosystem management. Through the analytical technique of fsQCA, five solutions were revealed, indicating that configurations of conditions contribute to ineffective ecosystem management, emphasising the combinatory nature of the challenges. Solutions across the dataset thus provide support for both propositions underlying this study. As there are multiple solutions for ineffective ecosystem management, the principle of equifinality is observed in this research, hence providing support for Proposition 1. The configurational nature of the core conditions, and the absence of any necessary conditions across all solutions, further confirms that no condition retains responsibility for ineffective ecosystem management (Proposition 2). Ultimately, it can be inferred from the findings that the challenges retain inherent complexities, exerting multiple and distinct effects upon the management of the ecosystem.

6.1 Theoretical contributions and implications

This study offers significant theoretical implications for the field of entrepreneurial ecosystems. With many existing studies adopting a comparative lens (Arruda, Nogueira and Costa 2013; Manolova et al. 2017; Voelker 2012) this study offers a methodological contribution through the application of fsQCA to the analysis of entrepreneurial ecosystems. While the application of fsQCA within ecosystems research has risen in recent years (Bacon et al. 2019a, b; Xie and Wang 2020) its usage for analysing challenges of university-industry partnerships across entrepreneurial ecosystems remains a key contribution of this research.

Moreover, while existing studies have examined the role of the university in an ecosystem context (Brito 2018; Meng et al. 2019; Miller et al. 2016; Lakitan 2013) limited research has explored the challenges pervading these relationships, and how they are overcome (Al-Tabbaa and Ankras 2016). Existing research has examined the barriers to university-industry collaboration (Bruneel et al. 2010) but not specifically in the context of entrepreneurial ecosystems. This study hence extends existing

debates of Bosco et al. (2018) through examining the challenges of the relationships between industry and academia within entrepreneurial ecosystems.

In identifying these challenges, fsQCA findings exhibited multiple, mutually exclusive pathways to ineffective ecosystem management. Despite some conditions retaining higher causal essentiality with the outcome, and hence requiring greater discussion, no condition exhibited necessity. Thus, it can be inferred that all conditions are sufficient, but not necessary, for ineffective ecosystem management. This study hence contributes to the existing ecosystems literature by providing potential explanations for high failure rates of ecosystem partnerships (Lauritzen and Karafyllia 2019). Moreover, extant studies highlight the interrelations between some challenges, such as trust and relational risk (Fulop and Couchman 2006) miscommunication and organisational distance (Wit-de Vris et al. 2019) and relationship disorientation and miscommunication (Steinmo and Rasmussen 2018), evidencing their mediating influences. While these studies suggest a likely configurational aspect to these challenges, this study confirms these associations, and others, through evidencing the configurational nature of all challenges.

6.2 Practical contributions and implications

Alongside theoretical contributions, this study offers important implications for practitioners engaging in university-industry collaboration within an ecosystem context. The configurational nature of the conditions confirms their influence upon one another, indicating that in circumstances where ecosystems are managed ineffectively, it is difficult to pinpoint exactly where the barriers lie. However, what can be ascertained is that, according to the core conditions, in terms of relational risk, it is either miscommunication or organisational distance inducing an effect. Cheng and Fu (2013) argue that well-defined collaborative relationships should be established when initiating an ecosystem partnership: through strengthening collaborative relationships, relational risk can be eliminated. With miscommunication presenting a key challenge, Sjödin (2019) endorses the usage of advanced ICT and group meetings with partners to increase the clarity and richness of communication within an ecosystem. Finally, with organisational distance incurring a greater likelihood of risk, organisations could consider creating events or workshops that would convey their own normative practices and operational mechanisms to potential ecosystem partners. Not only would this serve to diminish the degree of organisational distance between ecosystem partners, it could also potentially generate new partnerships within the ecosystem of connections. Increasing practitioner awareness of how to eliminate strategies is a critical starting point for eradicating key ecosystem challenges. Practitioners should hence be mindful of these influences and create further awareness of the fact that university-industry collaboration can impact upon the management of the ecosystem as a whole.

6.3 Limitations and future research

As with all empirical studies, a number of limitations pervade this research. Firstly, the sample size of this study is relatively small. While fsQCA possesses particular aptitude for small-n analyses, and the nature of the analysis mitigates the small sample size through the inclusion of logical remainders (see Ragin 2006), the authors still acknowledge that the sample size remains limited. Future studies could conduct similar analyses using a larger sample size. Secondly, as an exploratory study, this paper serves as an initial starting point for examining the challenges pervading university-industry partnerships in ecosystem contexts. Whilst grounded in empirical and theoretical evidence, only six challenges have been explored in this study; future analyses could ascertain whether additional challenges affect these partnership types, indeed achieved through conducting larger scale analyses to obtain a broader range of perspectives.

Additionally, the usage of fsQCA in this manuscript contributes to rising applications of this analytical technique in innovation-related disciplines (Kraus et al. 2018a, b). Despite recent applications of fsQCA to ecosystems research (Bacon et al. 2019a, b; Xie and Wang 2020) this paper offers a distinct contribution in utilising configurational analyses to explore ecosystem challenges pervading university-industry partnerships. Future research could also contribute to the rise of configurational techniques such as fsQCA, utilising configurational analyses to identify how constellations of conditions lead to ecosystem-related outcomes.

Finally, this study examines stakeholders' general perceptions of ecosystem challenges, without focusing on a specific ecosystem context. As such, future studies could investigate university-industry partnerships on more specific ecosystem types. Relatedly, as participants were obtained from different entrepreneurial ecosystems, albeit all UK-based, the vital role of geographical contexts within these ecosystems remains largely absent from this research. The authors again acknowledge that these regional influences did not arise as a barrier (nor, indeed, an inhibitor) for effective ecosystem management within the data collection process: nonetheless, ascertaining whether these challenges are apparent in regional entrepreneurial ecosystems, achieved through case-study analyses, comprises a fruitful avenue for further research.

Appendix A—Questionnaire items

Please indicate how much you agree or disagree with the following statements: (1 – totally disagree, 7 – totally agree).

Trust

To what extent do you agree/disagree that a lack of trust presents a challenge to ecosystem management?

Please provide an explanation for your response.

Relational Risk

To what extent do you agree/disagree that ecosystem partnerships present risks that affect ecosystem management?

Please provide an explanation for your response.

Relationship disorientation

To what extent do you agree/disagree that reluctance to engage in partnerships presents a challenge to ecosystem management?

Please provide an explanation for your response.

Organisational distance

To what extent do you agree/disagree that organisational differences between partners present a challenge to ecosystem management?

Please provide an explanation for your response.

Miscommunication

To what extent do you agree/disagree that miscommunication between partners presents a challenge to ecosystem management?

Please provide an explanation for your response.

Reluctance to innovate

To what extent do you agree/disagree that a reluctance to innovate presents a challenge to ecosystem management?

Please provide an explanation for your response.

Ecosystem management

Our ecosystem is effective in managing strategic contributions.

Our ecosystem is invested in by all members.

Our ecosystem evolves based on creating end-to-end experiences of customer value.

We implement community-level governance to our ecosystem.

Our ecosystem is aligned around shared intentions and a shared vision of the ecosystem future.

Author contributions All authors contributed to the study conception and design. Material preparation, data collection and analysis were performed by Dr ECB and Professor MDW. The first draft of the manuscript was written by Dr ECB and both authors commented on previous versions of the manuscript. Both authors read and approved the final manuscript.

Data availability Confidentiality was promised to participants, and hence complete raw data extracts are omitted from the article.

Compliance with ethical standards

Conflict of interest The authors declare that they have no conflict of interest.
